LONDON:
PRINTED AT THE "JOURNAL OF HORTICULTURE" OFFICE.
12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

INDEX.

- Abelia rupestris*, 133
Acacias, *dealbata*, 184; *leprosa*, 213; *verticillata*, 214
A common error, 86
Aconitums, 52
Acteas, 52
Ada aurantiaca, 38
Adenophoras, 173
Adiantums, treatment of, 56; culture of *cuneatum*, 271; for cutting, 527
Adonises, 173
Aërides, *nobile*, 430; *Houlletianum*, 435
Agapanthuses, 173
Ajugas, 173
Alliums, 236
Almond, common, fruit of, 510
Aloes, 27
A lost chord—Fenn and fungus, 41
Alpine flowers, 94, 221, 283, 496
Alströmerias, 236
Alyssums, Sweet, 253; a note on, 368
Amaryllis, at Chelsea, 379; at Aigburth, 393
American blight, 344, 383; and nursery-men, 26
Amsonias, 368
An amateur's reminiscences, 255
Anchusas, 368
Anderson, Mr. J., death of, 539
Anemones, *blanda*, 83; *Chapeau de Cardinal*, 226; *Crown*, 406; *sylvestris fl.-pl.*, 465; *nemorosa* varieties, 496
Angræcums, *Veitchi*, 48; *citratum*, 251
Anthocercis viscosa, 274
Antirrhinums in pots, 362
Ants, black, destroying, 38; small black, 56; and flowering Melons, 352
Apples, dessert varieties worth growing, 3, 61; comments on, 7; in Ireland, 7; for appearance, 37; scale on, 38; what is the record crop of, 47; Norfolk Bearer, 116; eggs on twigs of, 116; Royal Jubilee, 137, 144; for Perthshire, 195; *Sanspareil* 201; eggs on twig, 205; fire blight on, 212; Golden Noble, 213; imports and prices of, 251; Newton Wonder, 253; Northern Spy for stocks, 259; Northern Spy and American blight, 298; the bud moth, 345; Wanstead, 352; American Apple exports, 341; buds destroyed by birds, 375; twigs eaten just below the pruning cut, 374; buds, 396; and American blight, 383; insects on shoots, 419; shoots and leaves, 419; unsatisfactory, 480; English *v.* foreign, 490; destroying Apple Chermes, 539; white fungus on trees, 539
Apricots, triple buds on, 116; pruning, 137; successful outdoor fruiting, 284
April rains, 362
Arabis alpina fl.-pl., 496
Aralia Sieboldi, 339
Arsenic and vegetation, 64
Artichokes, Globe, 429, 485
Arum Lilies, thousands of, 368
Ashford Vineries, Cobham, 469
Asparagus culture, 60, 84, 230; notes 162, 125; for market, 136, 418; made in Germany, 146; selling, 459; Sprengeri, 464; dividing, 503; gigantic, 491, 529
Asters, annual, 160
A transformation, 240
Aucuba fertilisation, 214
Auriculas, 167, 199, 255; longevity of, 305; border, 305; *Auricula* and *Primula* Society Southern Show, 349; Northern Show, 407
Azaleas after flowering, 503
Balsams, 220
Beans, French, Syon House, 65; sowing Broad, 92; French Emperor William, 85; dwarf French, 145; (French) and Cucumbers diseased, 177; sowing Runner and Dwarf in boxes, 458
Bedding, preparations for, 207; old-fashioned plants for, 290
Bees, moving bees, 17; position of stocks, 17; protection of entrances, 36; shading the entrances, 36; securing roofs, 36; how England is supplied with honey, 36; attention to floor boards, 55; examination of stocks, 55; work in the apiary, 74; spare hives and frames, 74; skep overturned, 96; drones in hive, 96; how bees are destroyed, 115; destroying bee pests, 115; hives, 135; condition of stocks, 156; making candy, 156; seasonable notes, 176; using dark honey, 176; reducing entrances, 204; painting the inside of hives, 225; entrance blocked by dead bees, 225; spring dwindling, 246; early flowers, 246; the weather, 264; packing, 264; queenlessness, 285; present condition of stocks, 308; weak stocks, 308; rearing young queens, 329; commencing operations, 329; closing the entrance of hives, 351; feeding stocks, 351; seasonable notes, 374; snipers on hives, 374; spreading brood, 395; renewing combs, 395; effect of the weather on bee-keeping, 417; prevention of swarming, 417; commencing bee-keeping, 437; after management, 438; increase of stocks, 458; artificial swarming, 458; treatment of swarms, 479; working for a surplus, 501; work done in the apiary, 501; shading and ventilation, 521; comb foundation, 521; attention to supers, 538; extracting honey, 538
Beet, culture of, 344
Begonias, tuberous-rooted, from seeds, 18; *Gloire de Lorraine*, 74, 384, 538; *Haageana*, 85; *metallica*, 272; tuberous rooted, 287; leaves disfigured, 480
Berberis stenophylla, 384, 432
Bermuda, horticultural possibilities in, 304
Beschorneria tubiflora, 296
Biel House, 107
Birdlime, 136
Birds again, 365
Birmingham Gardeners' Association, 282
Blackberry cultivation, 355, 382; Parsley-leaved, 428
Blackberryland, Australian, 282
Blenheim, 192
Boilers, tubular, 287
Boronias, culture of, 369; *B. tetrandra*, 369
Botanic Gardens, old, 276
Botanic (Royal) Society—Spring Show, 297; summer show, 415
Bournemouth Chrysanthemum Society—Daffodil Show, 306
Botvardias, 185; propagation, 213
Box, variegated, and Yew, pruning, 226
Broccoli, late, 362, 491, 512, 539; a note on, 381
Brodieas, culture of, 391; *B. coccinea*, 391
Browallia speciosa major, 363
Brownea Crawfordi, 105
Browning or brunure in Vines, 52
Brunfelsia eximia, 317, 352
Bulb farming in Ireland, 422
Bulbophyllums, *barbigerum*, 250; *Ericsoni*, 293
Bullfinches, trapping, 83, 105, 126; protecting buds against, 136
Cactus hunt in mountain and desert, a, 361
Calanthes, *Veitchi*, 81; *Williamsi*, 269
Calceolarias, herbaceous, at Reading, 235
Callas, 370; *Elliottiana*, 451; *Pentlandi*, 451
Camellias, 197, 238; *Sasanqua*, 87; *roseiflora*, 165; *Mathotiana* and *M. alba*, 253; *reticulata*, 319; in tubs, liquid manure for, 480; at St. Leonard's Hill, 532
Campanulas, *soldanellaeflora*, 221; *planiiflora*, 283, 294, 496
Cannas from seeds, 165
Carnations, *Marguerite*, 84; planting, 157; rust on, 157; and *Picotees*, 167; the reign of the, 390; at Ickworth, 474; *Duchess Consuelo*, 489
Carpenteria californica, 489
Carrots, Sunlight soap for the prevention of the maggot, 383
Castor Oil Plant, 286
Cactleyas, *dolosa*, 5, 48; *Lawrenceana*, 232; *albino*, 315; *citrina*, 357, 381, 430; *Mossiae Reineckiana*, 401; *Mossiae Beauty of Bush Hill*, 470; *Mendeli*, 538
Cauliflowers, early, 85
Ceanothus Veitchianus, 339; *C. dentatus*, 339
Cedar, cutting back, 176
Celery, soft rot in, 177; culture of, 200
Celosias, culture of, 432
Ceylon, tropical growths of, 147
Chamærops, *humilis* at Padua, 276; *Fortunei*, 339
Chaff and grain, 82
Charcoal, 352; for Orchids, 103
Chemistry in the garden, 231
Cherries, *Morello*, 54; pruning, 116; for gardens, 190; forced, 350
Cherry house, the, 17
Chestnut, Spanish, burrs on, 330
Chiswick notes, 432
Choisya ternata, 297, 339, 465, 508
Chrysanthemums — propagating, 18; compost and manure for, 18; Mrs. M. Simpson, 13; traders, 13, 32, 51; problems, 13, 90; Mr. Briscoe Ironside in Italy, 9; Isle of Wight Chrysanthemum Society, 32; the N.C.S. prizes, 32; for Christmas, 37; N.C.S. executive committee, 50, 121; Wells' calendar, 50; feeding, 50; Archie Ray, 66; "Le Chrysanthème," 66; French certificated, 66; in the north of France, 66; N.C.S. classification of varieties, 66; the N.C.S. medal awards, 67; exhibits and medals, 68; rust in, 72; the N.C.S. and the Chairman's resignation, 89; Mr. Godfrey and the N.C.S., 89; awarding prizes at the N.C.S. shows, 89; incurved, 90; the N.C.S. and incurved varieties, 108, 142, 171, 219; complaints and grievances of the N.C.S., 108; the N.C.S. annual general meeting, 108; Australia and Mr. T. Carrington, 112; can it be true? 112; catalogues at shows, 112; Sheffield Chrysanthemum Society, 112, 142, 219, 402; Maidenhead Chrysanthemum Society, 122; in vases, 142; Mr. Wells' book, 142; The Egyptian, 142; late, 142, 171; cogitative notes, 188; the vase class at the N.C.S. Show, 219; Hull Chrysanthemum Society, 219; Kingston Chrysanthemum Society, 240, 252, 345;

CHRYSANTHEMUMS—continued.

and their culture, 240; seasonable notes, 280; Rugby Chrysanthemum Society, 280; belated plants, 245; leaves blackened, 396; incurved *v.* Japanese reflexed varieties, 402, 453; leaves diseased, 438; fungus on, 439; the final potting, 453; pinching, 486; discoloured leaves of, 538

Cinerarias, 296; notes on, 162

Circis siliquastrum, 473

Clandon Park, 426

Clematis indivisa, 105

Cleome heptaphylla, 18

Clerodendron fallax, 496

Climbers for back wall and ends of greenhouse, 37

Colax jugosus, 161

Coleus thyrsoidens, 85; seedling, 126

Coltsfoot, eradicating, 309

Commissions, illicit, 125, 259

Conifers not healthy, 226

Conservatories, lofty, climbers for, 352; at Walton Lea, 408

Costus igneus, 11

Cotoneasters, microphylla, 84; pruning, 264; bare, 286

County Councils and Gardeners' Improvement Associations, 419

Covent Garden Market, town *versus* country growers, 150

Cragg, Mr. J., death of, 467

Crassula coccinea, 272

Crocks, patent, 375

Crocuses at Hampton Court, 273

Crotons, growing, 242; is the Croton declining? 319

Crystal Palace fruit show, 26

Cucumbers, seasonable notes on, 17, 55, 73, 114, 155, 263, 351, 394, 437, 501; and Melons in the same house, 225, 331; roots knotted, 225; drooping disease in, 286; diseased, 330, 396; at Rowledge, 370;

Cypripediums, *insigne*, Harefield Hall variety, 5 315; *spectabile*, 56; *Wottoni*, 61; *Arthurianum*, 81; *Orion*, 151; *Sallieri Hyeanum*, 269; *bellatulum album*, 293; a floriferous, 61, 315; *bellatulum hybridum*, 357; *Wm. Lloyd*, 357; *Pollettianum*, 401; *callosum Sanderae*, 450, 470; *macrochilum giganteum*, 470

Cytisus scoparius Andreanus, 490

Daffodils at Ditton, 364; for amateurs, 363; in Midlothian (Valleyfield), 433

Dahlias, new, of 1898, 154; Mr. Mawley's analysis, 311

Daisies, double, from seeds, 400

Datura sanguinea, 438

Dean, Mr. A., presentation to, 491

Decorative helps, 267

Dendrobiums, *atro-violaceum*, 81; noble *Wallichianum*, 161; *nobile*, 209; *Boxalli*, 232; *hybridum*, 233; *Venus*, 233; *rubens grandiflorum*, 250; *Wiganæ*, 251; a note on, 251; *micans*, 292; *infundibulum*, 293; *Jamesianum*, 293; *subcausum*, 315; *Brymerianum*, 315; *Rolfæ roseum*, 335; *taurinum*, 430; *cretaceum*, 430; *Jenkinsi*, 430; *Johnsoniæ*, 485; *Wardianum album*, 514; *Falconeri giganteum*, 514

Deutzia gracilis, 4

Dendrochilum glumaceum, 351

Dickson, Mr. Wm., death of, 340

Dicliannus albus not flowering, 439

Ditton, notes from, 448

Doctors differing, 502

Dog's-tooth Violets not succeeding, 352

Domain, young gardeners'—Nerines, 16; Statice, 16; Euonymuses as greenhouse plants, 35; the culture of foliage plants, 35, 54; Euphorbia jacquiniæflora, 54; Tomatoes, 72; the Fig, 72, 94; Gloxinias, 94; Gold penmen, 114; Cucumbers, 114; a pupil of an Old Boy, 114; Mushroom culture, 134; Melons, 134; forcing Lily of the Valley, 154; Gladiolus The Bride, 154; Ixoras, 154; young men's dreams, 174, 244; our friend the toad, 174; a homily, 202; Vine culture, 202; early Peaches and Nectarines, 202; double Violets, 223; Strawberry forcing, 223; Begonia manicata, 244; the Gloxinia, 244; Seakale, 262; French Beans, 262; decorative Chrysanthemums, 262; a word of thanks to Mr. D. Thomson, 284; Libonias, 248; Onions, 284; drainage and compost, 284; the Lachenalia, 306; Asters and Stocks, 306; Grevillea robusta, 306; a word to the wise, 327; formation and cropping of a kitchen garden, 328; the Gooseberry, 350; New Zealand Spinach, 350; Asparagus in beds, 372; watering, 372; Fuchsias, 372; the shrubbery border, 394; Dahlias, 394; the tuberous-rooted Begonia, 416; Welton House Gardens, 416; Carrots, 436; Celery, 436; summer bedding, 457; newly planted Apricots, 457; Chrysanthemums, 478; Freesias, 478; Bouvardias, 500; Celery culture, 500; exhibition vegetables, 520, 537

Dornden, a note about, 448

Drummond, Mr. P., death of, 494

Dry but important, 505

Dublin, notes from, 472, 517

Dunn, Mr. Malcolm, death of, 412; memorial fund to, 510

Dyer, Sir W. T. Thiselton, 33

Echeveria metallica, 319

Eelworms, 93; corrosive sublimate for, 37; and silico-fluoride of ammonium, 34

Embothrium coccineum, 321

Epacris, culture of, 347, 502; *miniata splendens*, 347; *elegans*, 347

Epidendrum, Wallisi, 161; *Endresi*, 209; *varicosum*, 357; *elegantulum luteum*, 381

Epiphronitis Veitchi, 514

Eremurus himalaicus, 469

Ericas, *hyemalis* and *Willmorei*, 214; and their culture, 303; *E. propendens*, 303

Error, a common, 86

Erythraea Massoni, 221

Erythrina crista-galli not flowering, 438

Erythrochiton hypophyllanthus, 106

Erythroniums, Hartwegi, 94; *americanum*, 221

Eucalyptus, globulus in tubs, failing, 157

Eucharis, notes on, 162, 213; *amazonica*, 252

Eulalia japonica, treatment of, 19

Euphorbia mellifera, 428

Eurycea Cunninghami, 38

Eutoca viscidula, 519

Examinations in horticulture, 526

Experimental horticulture, 270, 316, 345 360

"Familiar Wild Flowers," 317

Farm—Feeding sheep in winter, 19; a short review of 1898, 39; an old subject, 57; feeding cows, 58; a full

FARM—continued.

milk pail, 75; advance Ireland, 97; feeding cattle for market, 117; sheep for mutton, 137; a treat for dinner, 157; books on cows, 158; small proprietors, 177; horses for pleasure and profit, 205; field Cabbage, 227; National Poultry Test, 228; poultry, 228; the French dairy interest, 248; what is the value of the new Adulteration Bill? 265; condensed milk, 287; American egg competitions, 309; the Mangold Wurtzel, 331; May, 1823, 353; butter from the Antipodes, 375; malt culms, 376; two feathered friends, 397; manures for Swedes, 419; stud babies, 439, 460; a South African industry, 481; Rabbitland, 503; beer drinkers and brewers, 523; Herefordshire and Worcestershire Agricultural Society, 524; agricultural returns for 1898, 539; work on the home farm, 20, 40, 58, 76, 98, 118, 138, 158, 178, 206, 228, 248, 263, 288, 310, 332, 354, 376, 398, 420, 440, 460, 482, 504, 524, 540

Faults, fallacies, failures in fruit culture, 189, 277, 300

Fenn, Mr. R., 530

Ferns, improving colour of, 247; temperature for Maidenhair, 247; weevils on, 502; out of doors, 516

Fields of waving gold, 364

Figs, seasonable notes on, 17, 92, 171, 215, 280, 348, 404, 452, 528; outdoor, 224; in pots, 325; hard substance at the eye of, 352; leaves and fruits rusted, 502

Filbert culture in Italy, 349

Finger-and-toes, Devon experiments with, 104

Flatland, 424

Florists' flowers, seasonable notes on, 167

Flowers, hardy, 188; in February, 140; border, 173; for the workers, 235; spring, 281; of the West, 282; some edible, 296; hardy, in April, 323; when flowers sleep, 319; perennial border, 368; among the hardy, 379, 462; cut, care of, 477; night-scented, 477; in dry weather, 507

Flowing tide, the, 249

Forcing pit, temperature for, 97

"For gardening and gardeners," 187

Forsythias, 349

Fortune, Robert, plant collector, 411, 434

Fraxinus Ornus, 481

Freesias, and their culture, 12; out of doors, 383, 398

Fremontia californica, 489

Frosts, March, 354; May, 449

Fruit—Hardy fruit garden, 16, 54, 95, 134, 175, 224, 263, 307, 350, 395, 436, 478, 520

Fruit forcing, 17, 35, 55, 73, 95, 114, 135, 155, 176, 203, 224, 245, 263, 284, 307, 328, 350, 373, 394, 416, 437, 457, 479, 501, 521, 537

ANT. ROOZEN & SON'S SPRING CATALOGUE

For 1899,

OF

Vegetable & Flower Seeds

AND

BULBS & PLANTS

IS NOW READY.

Will be sent Post Free on application to their Offices at OVERVEEN, near HAARLEM, HOLLAND, or to their GENERAL AGENTS—

Messrs. MERTENS & CO.,

3, CROSS LANE, LONDON, E.C.

No. 967.—VOL. XXXVIII, THIRD SERIES.

THE CHAMPION NEW TOMATO FOR 1899.

Webbs' "CHANCELLOR."

Amongst the many Tomatoes already in commerce, this variety will be a decided acquisition. The fruit is of fine shape, large, smooth, and bright red in colour, the flesh being thick and of agreeable flavour. It sets its fruit freely, and is a heavy cropper.

1/6 & 2/6 per Packet, Post Free.

For full particulars of Novelties and Specialities see Webbs' Spring Catalogue, beautifully Illustrated and enlarged to 136 pages, post free 1/-. Gratis to Customers.

WEBB & SONS,
Wordsley, Stourbridge.

The 31st Edition is Now Ready.

200 PAGES. 150 ILLUSTRATIONS.

PRICE SIXPENCE, POST FREE.
(By Parcel Post—it is so large).

EVERY AMATEUR SHOULD POSSESS A COPY.

CONTENTS.—The Best Seeds and Potatoes for Garden and Farm; also Descriptive Lists of Carnations, Chrysanthemums, Dahlias, Fuchsias, Gladioli, Herbaceous Plants, Pansies, Pelargoniums, Phloxes, Pinks, Pyrethrums, Roses, and Violas, with full Cultural Directions for each.

LONDON, S.E.—“Please accept my best thanks for your Catalogue. It is a most useful and beautiful work, giving more information suitable to amateurs than many more expensive works.”—G. B.

NORWICH.—“Your Catalogue is the best I have ever seen. It has been an invaluable guide and help to me.”—H. H.

WOLLASTON.—“I received your Catalogue, for which please accept my best thanks. It is a splendid book, and contains cultural directions which are a great help to amateurs.”—J. B.

Apply Early, and please mention this paper.

Journal of Horticulture.

THURSDAY, JANUARY 5, 1899.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

NEW YEAR'S ADDRESS.

“WHAT, at it again?” I hear some cynical friend calling out; “I really think it is time that that old fellow left off and made room for others to take his place; his pen must be pretty well worn down to a stump, and his ink thick and muddy—thoroughly emblematic of his ideas.” Well, so I thought; but the Editor does not share my views, and using some flattering words, asked me once more to send a message to the ever increasing number of the readers of the Journal. So I have acceded to the request, the more readily as it has now well advanced upon the fiftieth year of its existence, during nearly forty of which I have been a regular contributor.

When I was meditating on this I saw some very cheering observations made in the pages of a contemporary, in which we were told that the number of successful contributors to gardening papers might be counted on the fingers of one hand! I could not even claim, then, to be a little finger, and must be content with whatever measure of praise or blame a considerate clientele may give me.

There is one difficulty in writing on the horticulture of the past year—that we have no startling events to record; nothing, for instance, like the Jubilee of her Majesty and the consequent installation of the Victoria medal for horticulture; and as it would be difficult to say anything of a country which has no annals, so equally difficult is it to record the doings of a science in which all seems to go on in a smooth regular course. There is, however, one subject which closely affects us all, and especially gardeners, and that subject is the weather.

Do you ever shake hands with a friend in the streets without his immediately saying to you, “A fine day,” or “Very cold,” or “Very damp,” or something relating to the state of the atmosphere?—a sure indication, as someone has said, of the uncertainty of our climate; and I think we may safely say that (in some parts of the country at any rate) gardeners have had a fearful time of it. We have experienced another year of drought, and

in many places the question of the supply of water for domestic uses even has altogether failed. Springs which were never before known to fail have given in; wells have become useless, and ponds dried up. So much so has this been the case that Lord Onslow had to leave his residence in the Surrey hills and come to his town house, because his supply of water had altogether failed.

What chance then has our poor plants had? To draw water even from a little distance adds much to a gardener's labours, but when it has to be fetched three, four, and five miles, it is clear the gardens must suffer much; and so it has been in this year of Grace 1898, but not in all parts of the country. The east and south have been the chief sufferers, and no better idea can be formed of the difference between various parts of the country than that afforded by the fact that during the three months—August, September, and October—the rainfall in S. Wales amounted to upwards of 15 inches, and in East Kent to 4 inches.

All through it has been a year of disappointments. Nothing lovelier than the appearance of the orchards in their blossoming time can possibly be imagined; the Plum and Cherry orchards with their snow-white garb, and the Apples with their pink-tinged flowers afforded a dream of beauty not to be forgotten. But alas! the promise was far greater than the performance. Everywhere we found the same complaints—Plums and Cherries a complete failure, while Pears and Apples were only a tithe of what they generally are, and the same was true about flowers.

The Rose gave promise in the earlier part of the year of a grand season. We had no frost or snow of any consequence, and everybody looked forward to an early blooming season; but there came a long spell of drought, accompanied with harsh winds, and the hopes of Rose growers were blighted. I take the National Rose Society as a pretty sure index. Its show at Bath was the smallest southern provincial show that was ever held, and the Crystal Palace was comparatively small in extent, and the one adjective that was used by Rose growers as to the season was that it was very disappointing.

The prolonged dry weather which we experienced in some parts of the country destroyed the hopes of those who look to the embellishment of their gardens by annuals; they could not grow, and consequently did not bloom. Those who had not gardens looked upon the season with very different eyes; the dry weather meant for them long tours on bicycles, pleasant afternoons at lawn tennis or croquet, and out-of-doors enjoyments of all sorts.

In reviewing the horticultural events of the past year our attention is, of course, first fixed on that which is the great centre of horticulture in these islands—the Royal Horticultural Society. Time was when this was a dangerous theme to touch upon; there were so many shoals, quicksands, and rocks ahead that it would have required no small amount of courage to venture into the stormy sea. Happily, all this is changed; its energies are now devoted to the interests of horticulture; its Council has only to think how best those interests may be promoted; it is composed of men thoroughly alive to this, and under the guidance of their able and genial Secretary (whose views are like theirs) they are continually putting forward some new schemes for the advancement of horticulture. It is true that there has been no such project before it as the most gracious one that they carried out last year in the establishment of the Victorian Medal for Horticulture, but they have added this year to the graciousness of their act by presenting each of the recipients with a diploma of honour.

The garden at Chiswick has been greatly improved, and though probably too much surrounded by houses to carry out its experiments and trials in as satisfactory a manner as might be wished, still there is much of interest in what is being done there. The fortnightly meetings in the Drill Hall have probably been better filled with plants, flowers, and fruit than any previous year, while the attendance has certainly been somewhat better.

The grand vision of a Horticultural Hall seems to have vanished into thin air. One felt that when the first effort, inaugurated by

Baron Schröder and other leading men, fell through, that it must be so, for the only available site was lost, and then those who advocated it in providing a hall hardly knew what they wanted, and so the Royal has been compelled to put up with a very indifferent place, with very inartistic surroundings. The National Chrysanthemum Society has to put up with that noisiest of all places, the Royal Aquarium; an attempt was made this year to remove the Chrysanthemum Society to the Crystal Palace, but the subscribers would not have it, and one sees that there are difficulties in the way. It is not an easy matter at any time to get garden produce up Sydenham Hill, but when it has to be accomplished in the depth of winter the task is made still more difficult and unpleasant.

The Crystal Palace, all the same, still holds its own as the place for exhibitions. Its light and protection from the elements combine in asserting its superiority, and under the new management it looks as if there would be improvement in every direction. There the National Rose Society held its grand exhibition; there, too, the National Dahlia Society gathered together a grand show, while the autumn exhibition of British grown fruit under the auspices of the Royal Horticultural Society, made its magnificent display, and there is every prospect of the year 1899 carrying forward its best traditions.

The Royal Botanic has made a strong bid for popular favour, but it does not seem as if that would be brilliantly successful. The National Carnation and Picotee Society has suffered loss by going there, and was this year removed to the Crystal Palace with manifest advantage. It is a great pity, for the gardens so ably laid out by Robert Marnock are yearly increasing in beauty.

Of course the palm of metropolitan exhibitions is carried off by the Royal Horticultural Society's show in the Temple Gardens. This was held as usual at the end of May, and was a great success in every point of view; the weather was very fine, and there was a magnificent display of plants and flowers of all kinds, and from all parts of the country. There is, it is true, little change from year to year, and one can pretty well tell before entering the ground, where the principal exhibits are to be seen. This is probably a necessity. There is, however, one point in which improvement might be made—viz., the setting up so many duplicates, and the consequent contraction of space for the more remarkable exhibits; it was also financially a success, and the resources of the Society have thereby been improved.

Though there have been no very startling novelties brought forward either in plants or flowers, the most remarkable plant has been *Acalypha Sanderi*. It was brought forward by the well known St. Albans firm; it is a greenhouse shrub, producing long crimson panicles in the axils of each leaf, reminding one very much of the old garden annual, *Love-lies-bleeding*. But doubts have been expressed as to its really being a novelty, it being said that it has already been introduced into our gardens under another name.

While I think we may take the awards of merit granted by the Royal Horticultural Society at their fortnightly meetings as comprising most of the best flowers of the year, this does not hold true in all cases, chiefly when there are especial societies for the culture of each particular flower. Take for example the Rose. As far as I can recollect no gold medal Rose has received an award at the Drill Hall; the raisers of new varieties will rather submit them to a committee of the National Rose Society, and their awards are highly prized. Messrs. Alexander Dickson & Sons of Newtownards have never exhibited any of their grand seedling Roses there. So, again, with Chrysanthemums. There are many of these flowers brought forward at the National Chrysanthemum Society's exhibitions which do not come before the Floral Committee of the R.H.S., the "certificate" given by that Society being more valued than an "award of merit" by the other.

The reason of this is not far to seek. The Floral Committee is composed of men many of whom know nothing of florists' flowers, while in the special societies already named the committee is composed of those who are experts in the flower on whose merits they

have to decide. The class of flower to which the greater number of "awards of merit" have been given follows the lines of the last few years. We have the Orchids, which may be called the rich man's flower; at the other end of the scale the Chrysanthemum, which is *par excellence* the flower of the poor man. The former can only be successfully cultivated by those who have a good staff of gardeners, while the veriest shanty can so well protect the Chrysanthemum that a cottager may grow and exhibit them, and, as I know, carry off prizes from those with much ampler means at their disposal.

In looking through the list, then, I find that "awards of merit" were given to seven Cypripediums, seventeen Cattleyas, ten Lælias, sixteen Lælio-Cattleyas, nineteen Odontoglossums, and seven Dendrobiums—in all sixty-nine, a pretty good record; and the question naturally arises, Are these all sufficiently distinct to justify the Committee in giving them these awards? In former days—and I am not sure it is not the same now—florists were roundly rated for considering various flowers distinct in which it was said no one but the raiser of it could have seen any difference. Botanists especially dealt very hard blows on us, and it is a grim satisfaction that they now are sorely perplexed as to what to do with the many new varieties resulting from cross-hybridisation. The same may be said with regard to Chrysanthemums. There are multitudes of flowers in which the difference between them and those already in cultivation is not easily distinguishable; but there are a few of remarkable merit, such as Lord Cromer and H. J. Jones, which promise novelty and brightness of colour, and will no doubt be generally acceptable and much used for exhibition. We have whites and yellows in abundance, and require something now to brighten up our stages and greenhouses.

There have been some striking additions in Cactus Dahlias, while Mr. Engleheart's Narcissus show how much can be done by a careful and painstaking hybridiser. The Gladiolus does not seem to receive so many awards as usual, although Mr. Kelway of Langport and Mr. Burrell of Cambridge have exhibited some striking novelties. When one sees the splendid collections shown by these gentlemen I was tempted to ask, "Why is not the flower more popular?" The only answer I think to this is that they entail a great deal of trouble if they are successfully cultivated, and also the fact that so many of them fail each year.

Neither do I think there is much to record in garden literature. The weekly periodicals seem to flourish, and I do not think anyone can say the Journal lags behind, and I think its Editor may well be satisfied with the high position it occupies amongst its fellows. We miss, it is true, the productions of many a facile writer, but then there are others who come forward to take their place. I cannot but think that many more of our younger men might train themselves in giving to the gardening world the results of their experience.

In general garden literature we have had but few additions. A chatty and pleasantly written book on Roses at Cannes has been given to the world by Lord Brougham and Vaux, who does not profess to give a new treatise on the culture of the Rose, but only to describe them as they grow in that favoured locality; and one reads with feelings akin to envy of the marvellous bushes and trees of Teas and Noisettes especially which there delight the cultivator if he can avail himself of the deep rich soil and sunny skies. It has, of course, its drawbacks; Hybrid Perpetuals are not such a joy there as they are with us; but during the spring months the Teas and Noisettes must afford a treat of which we can have no idea in our colder climate.

During the many years in which I have been permitted to send this message to the readers of the Journal, I never remember one in which the death roll has been so small. Many of those who have left us during the past year do not form such a blank in our daily life as was the case with some of those whose death we had to deplore in former years; in truth, the best known amongst them was Mr. James Bateman, whose death belongs really to last year, he having died on November 27th, 1897. He was for many years a conspicuous member of the Council of the R.H.S., the pioneer in the

more rational treatment of Orchids, of which he had a large collection at Biddulph Grange, and a ready speaker in all matters connected with horticulture. Mr. Pullham of Broxbourne, a man whose artistic tastes had been much called into requisition by those who were forming artificial rockeries in their gardens, while his successful arrangements at Battersea Park and other public gardens brought him into the prominent notice of the public. The name of M. Jean Linden, at Brussels, recalls to mind one of the most energetic and accomplished of foreign horticulturists. Many of our countrymen, like myself, have shared his hospitality, and know how great a loss his death is.

The Horticultural Club, which has now for so many years formed a bond of social union amongst horticulturists, both amateur and professional, has continued its useful career; its rooms afford a meeting place for societies of various kinds, while its monthly dinners and conversaziones have been greatly enjoyed and well attended, and the papers read and discussed at its meetings have been of a valuable character. Most of them have appeared in the gardening periodicals; it affords an opportunity also for welcoming foreign horticulturists, and in the coming year will be further utilised in welcoming those distinguished foreigners who may attend the conference on hybridising, inaugurated by the Royal Horticultural Society.

And now, my brothers and sisters—ought I not rather to say sons and daughters?—to whom our gentle craft has given so much pleasure in years past, suffer a word of encouragement from one who has, as he has often told, derived intense satisfaction and enjoyment from his flowers. Of course the enthusiasm of former years has cooled down, but still, in the evening of his long day, there is an immense amount of quiet enjoyment to be had. I say to you then, Go on and prosper; cultivate your gardens and enjoy your flowers without reference to medals, cups, pieces of plate, or money, and whether you go amongst your flowers when spring has contributed its beauties to your enjoyment, or summer has loaded you with its treasures of sight and perfume, or even when autumn has shattered your favourites, learn such lessons for your daily life as may the better fit you to be ready for that call which comes to us all, so that you may look forward to that Paradise of God which has been won for us by Him who is the Rose of Sharon and the Lily of the Valley.—D., Deal.

APPLES WORTH GROWING.

(Continued from page 434, December 8th, 1898.)

I MAY first mention that the garden is about 350 yards from the bank of the river Humber, and about five miles west of Hull. When there are high spring tides the bank is often covered with water. The garden slopes a little to the south. The formation is chalk. Between the chalk and the surface soil (of 5 to 8 inches in the fields) there is a bed of hard dull red hungry clay 6 to 8 feet thick—not an ideal soil for fruit culture, as will be admitted. The red clay of Nottinghamshire, where fruit does well, is of a bright red. To plant Apples here and give them the best of care afterwards will not give results equal to those from Apples planted in the Cray valley, Kent, and which practically receive no attention after the soil has been well worked before planting, and keeping it loose on the surface afterwards.

Most of our Apples are grown on bush trees—young trees bought from the nursery. Standards appear to be of little use in comparison. There is an orchard of standard trees at the farm about 300 yards from the garden. The trees have been neglected, and the varieties are inferior. Those trees do not half pay what would be a reasonable rent for the ground that they stand on. We grow some cordon Apples on the walls from maidens of the newer varieties. I have had orders from my employer to grub up all the Peach and Apricot trees growing on the walls through planting about forty cordon Apples two years ago, and to these are now added fifty Cox's Orange Pippins. In value the crops of Peaches and Apricots bear no comparison with that of the Apples.

When a young bush tree three years old is bought from the nursery its training is only then begun. After that the tree can either be ruined for fruit bearing, or made productive and valuable. See the notes from "Nurseryman" on page 452, December 15th, they are very true. Some of the bush trees here planted alongside the garden walks have grown to the height of 9 to 12 feet, with their centres open and

the branches thinly trained, some of these nearly extending across the path through pruning to outside buds. I keep all old worn-out spurs cut away.

VARIETIES OF DESSERT APPLES.

My object in writing the few notes on dessert Apples is partly to redeem from oblivion, if possible, some of the most delicious Apples that we have for private use. Others I have mentioned are good for market. The small varieties require superior culture to bring out their best qualities. The larger varieties will produce Apples of fair size for market without much trouble, but where is the quality? I know that ladies and gentlemen appreciate an Apple of good quality.

Cox's Orange Pippin.—Season, November to March. I should be glad to learn that there were being planted in every garden from one to a hundred trees of this splendid dessert Apple, either as bushes, standards, or cordons, according to locality and convenience at command for growing them well. If there is a space 18 inches wide on a good wall, plant a cordon Cox. You will be rewarded, only give the tree a chance at the roots. It is seldom that a good dish of this Apple comes from the dining-room table intact, though good Grapes are often untouched at dessert.

Culture of Cox's Orange Pippin.—Plant in a sheltered, yet sunny situation. If there is a depth of 18 inches of good soil, that will suffice. Have some turf or other fresh fertile soil mixed with about a sixth part of burnt garden refuse to plant with. Do not plant deeply, but somewhat near the surface. Stake at once, and mulch with half-decayed manure 2 or 3 inches thick. As the trees grow keep the branches thinly trained, and when they are bearing good crops of fruit give liquid manure at intervals throughout the year; also half a pound of basic slag to the square yard in November, or 1 lb. of superphosphate to 3 square yards in December or January, pointing-in 2 or 3 inches deep.

Ribston Pippin.—As a dessert variety for private use this old favourite is highly appreciated when well grown. I have found that liberal treatment serves to ward off mildew and canker, which is incited by starvation at the roots, plus negligence or mismanagement generally. Some years ago I took charge of an orchard that included two half-standard Ribston Pippins amongst its tenants. The trees were the reverse of satisfactory; the branches crossed each other and were covered with lichen and moss. The heads were thinned, the stems scraped and dressed with soot and lime, fine lime being also thrown amongst the smaller branches when they were wet; the roots were assisted by liberal supplies of liquid manure winter and summer. All the trees were similarly treated, but the Ribstons and a few others had a couple of light dressings of guano. The soil was only 8 or 9 inches deep on limestone. The second year great improvement was apparent all round; the third year the Apples were first-class for an orchard with thin soil. In the winter of the third season I sent in a dish of Ribstons for dessert. The dinner party included a gentleman possessing good knowledge of the Apples; but he said the name was not right, as the colour was too high for Ribston. I sent some of the Apples to the late Dr. Hogg for his opinion. His answer was, "The true Ribston, well cultivated." So much for generous treatment. The trees had been starved in the thin soil, and its resources wasted on a number of useless branches with a crowd of apologies for leaves. That was in Lincolnshire, a district not famed for fine Apples.

Golden Winter Pearmain.—This is, I think, the correct name of King of the Pippins. Season, November to January, or later. This appears to be a favourite Apple with many people. The fruit assumes a lovely colour under good cultivation, and though neither large nor rich sells well. The tree is a free, healthy, upright grower, and requires careful pruning to outside buds to cause the shoots to grow away from the centre. It is one of the most reliable when the branches are thinly disposed and worn-out spurs removed.

Worcester Pearmain.—Season, September to November. A popular variety because of its colour, but more so with market than private growers, for in quality there are many better varieties. I grow it for sale because buyers like it, and that is enough for me. The tree is not a large grower, but a regular bearer. It requires heavy feeding here, and bold healthy spurs for producing full-sized and well-coloured fruit.

Baumann's Red Winter Reinette.—Season, November to February. Another fair-sized, deeply coloured, and therefore popular market Apple. The tree is a good grower and bearer. It will look after itself, so to say, better than some others, but will well repay for the best cultural treatment. For home use I would not grow it either for dessert or cooking, but when we want other people's money we must consider other people's fancies, or we shall get very little in the market.

Lady Sudeley.—Season, September and October. One of the best early Apples, with size, colour, and flavour to recommend it, while the tree is a good grower and bearer. An excellent Apple for market and private use. The fruit has a greenish-yellow skin striped with red, and the flesh is tender and enjoyable under good culture. When

the trees are formed, thinning rather than shortening the branches, should be the rule in pruning.

Allington Pippin.—Season, November to January. A comparatively new Apple of fair size, fine appearance, and excellent quality. I think it originated in Lincolnshire from Cox's Orange Pippin. The tree is a good grower and bearer, and likely to be extensively planted for affording supplies of fruit both for the home dessert and market purposes.

Gravenstein.—Season, November to January. Why is not this beautiful Apple more frequently seen? Are all the trees sold true to name? I think I have seen some that are not. The fruits are above medium size, good alike for cooking or dessert, and the waxen-yellow skin, deepening to orange and sometimes faint crimson, renders them attractive. The flavour is good at Christmas. Succeeds well as a standard in good soil and a warm situation. When well grown there is no difficulty in selling the fruit. Give phosphatic rather than nitrogenous food, and the fruit will be improved in colour and flavour. Liquid manure is always acceptable by free bearing trees.

Kerry Pippin.—A little gem for private use, and comes in well for the early shooting season. From September to November. The tree is a rather small but healthy grower. The fruit is much like Golden Winter Pearmain in colour, but of decidedly better flavour. These small growers require their fruit well thinning and the roots liberally treating for affording the best of fruit.

Margil.—Season, November to February. This first-class dessert Apple is suggestive of a smallish Ribston with soft flesh. The tree is a small grower, and on poor soil subject to canker. Do not allow the branches to become crowded; thin out old spurs, and give the best of culture, then you will have an Apple worth eating—a Ribston flavour, and something more.

Trumpington (syn. *Eve Apple*).—Season, September to January. I find this to be a delicious little Apple at midwinter for private use, but should not grow it for market. The skin is striped with pale red on the shaded side, but covered with bright red in the sun, so much so that I have occasionally seen the tender flesh coloured nearly all through. The tree makes a good half-standard, and perhaps succeeds better in the north than the south, as I have the fruit described as "second-rate."

Irish Peach.—Season, August. Everyone connected with the garden probably knows that the fruit of this early Apple is best eaten directly it is gathered. The tree requires good cultivation. The roots must not be allowed to get down into a cold clay. Care is required in pruning, because many fruit buds are formed on the current year's growth. Thin out the old spurs and keep the wood thinly trained, also thin the fruit when crowded, and then you may have it in the best condition.

Dutch Mignonne.—Season, December to April. The fruit of this not extensively grown Apple is of good dessert size and handsomely shaped; the tree is a free grower and bearer, and makes a productive bush or half-standard when branch crowding is not permitted. When the fruit is well grown and ripened the flesh is yellow, and I have had it of first-class quality in April. An excellent Apple for private use.

Lord Burghley.—Season, January to June. One tree at the least ought to be found in every garden of any size. The fruit is of good appearance, medium size, with a flush of red next the sun, and the flesh is of Pine Apple flavour. Keep the roots out of the subsoil and the branches thinly trained, then with a fair amount of phosphates added to the soil, with manure when the crops are swelling, the best of fruit may be obtained. Sturmer Pippin is not worth growing, as compared with Lord Burghley, in Yorkshire as a late dessert Apple.

Old Nonpareil.—Season, February to May. Just the Apple for private use in the spring. The tree is a small grower, the fruit requires thinning to obtain a fair size.

King of Tompkins County.—Season, December to March. A large, well-flavoured, soft-fleshed Apple. Tree a very strong grower. I have grown three cordons on a south wall, and they have given much satisfaction.

Blenheim Pippin.—Though I consider this Apple of excellent dessert quality, I cannot recommend it for quick returns as a bush. For a permanent place, with good soil, plant Blenheim as standards, wait till it bears, and it will give approved fruit for a generation.

All the varieties mentioned will appreciate a mulching of manure over their roots in summer.—GEO. PICKER.

DEUTZIA GRACILIS.—Plants of these intended for forcing are best placed in frames previous to taking them into heat. If introduced direct from the open into strong heat the buds are liable to be blind. From frames the plants may be placed in a greenhouse of 45° to 50° temperature. This will cause the buds to swell gradually, and when further advanced, or about to burst, give a moist atmosphere in a temperature of 60° to 65°.—D.

CYPRIPEDIUM INSIGNE, HAREFIELD HALL VARIETY.

THE number of varieties of *Cypripedium insigne* grows greater year by year, and the enhanced beauty of some of the present-day forms in comparison with the type is most striking. Some are remarkable for distinctness of colour, as, for example, *C. insigne* *Sanderæ*, while many combine size with other attractive points. Coming within this latter category is the one represented in the accompanying woodcut. This variety was exhibited by Mr. H. Holbrook, gardener to E. Ashworth, Esq., Harefield Hall, Wilmslow, at the Dill Hall on December 13th, 1898, when the Orchid Committee recommended a first-class certificate. A glance at the representation (fig. 1) will convey an excellent idea of the boldness of the flowers, which are carried on stout footstalks well above the proportionately strong leafage. The most attractive organ is the dorsal sepal, it being quite 3 inches across the centre. The central portion is pale green heavily spotted with chocolate, all round the outer portion of which is a broad margin of pure white. The pouch and petals are yellowish green with veins of darker green, and suffusions of brown. The Harefield Hall variety of *Cypripedium insigne* will be adjudged by all who see our illustration one of the handsomest forms extant.

ODONTOGLOSSUM ROSSI.

Although, excepting a few rare varieties, this species is looked down upon, it is one of the most useful of cool house Orchids. It keeps up a long continued winter display, and the flowers are wonderfully varied. The plants do best in small pans suspended from the roof, but if this is not convenient they will grow well and flower annually on the side stages of the cool house, which are as a rule not very far from the glass. Quite ordinary compost and general treatment suffice, and the flowers last as long as any in the genus, not excepting the well-known *O. maculata*.

It is named after a collector once in the employ of Mr. Barker of Birmingham, and it flowered in his collection soon after its introduction in 1837. The typical form has whitish flowers spotted with reddish purple all over the sepals and on the basal half of the petals, the lip usually yellow streaked with red. Beside this there is a bright coloured form, *O. R. rubescens*, having rosy red segments spotted with reddish brown; *O. R. aspersum*, thought by some authorities to be a natural hybrid between *O. Rossi* and *O. maculatum*, and having a good deal of the yellow of the latter; *O. R. coerulescens*, *O. R. Warnerianum*, and many others more or less distinct. Many collectors have sent it home since its introduction, and all who have met with it agree as to its great variability in its native habitats.

CATTLEYA DOLOSA.

This is a charming *Cattleya* not at all popular, or indeed known. It is strange that it is not more often sent home by collectors, for there are not many plants of its size that produce such fine showy blossoms. It has been described as a variety of *C. Walkeriana*; but from a garden point of view, at any rate, it is quite distinct in its habit and manner of flowering, the blossoms occurring on a scape from the centre of the growth instead of upon a separate growth, as in the older species. Like *C. Walkeriana*, it has broad overlapping side lobes to the lip, this organ being a rosy purple of a deeper shade to that on the sepals and petals. Plants of it do well in the ordinary *Cattleya* house temperature, suspended not far from the roof glass in pans or baskets. Equal parts of peat fibre and sphagnum moss over good drainage suits it well, and a fairly long but not dry rest is required. In all cultural details otherwise it may be treated like the labiate kind. We should be glad to hear of any Orchid readers of the *Journal of Horticulture* who have been successful in its culture, with particulars of treatment followed.—H. R. R.

LONDON GARDENS OVER FIFTY YEARS.

THERE was a worthy London citizen of the olden time, his name I cannot recall, who knew the metropolis when it was but of moderate dimensions, and in his admiration of it he compared London to Zion of ancient days, calling the city "beautiful for situation, the joy of the whole earth." We like his enthusiastic love of this city, the more, perhaps, because now such a sentiment is not as common as is the propensity to find fault with one's place of abode. Whether London was then the "joy of the earth" may be doubtful, but since it has undeniably become a centre of attraction, drawing people from every land. "Beautiful for situation," this was true of the mediæval city, and even yet, despite the enormous growth of the metropolis, some charming bits of scenery have escaped the road maker and builder.

Situated in a fertile valley, with the ground rising into hills both north and south of the Thames, old London was largely sheltered from gales by the extensive woods that lay around, amongst which here and

FIG. 1.—CYPRIPEDIUM INSIGNE, HAREFIELD HALL VARIETY.

there stretches of heath or common occurred. Another advantage it had was the numerous rivulets and brooks which flowed from the uplands. By-and-by there came a change with the progress of horticulture after the seventeenth century; orchards and gardens increased around London, but they did not spoil its vicinity, though it became less rural. Green spaces still separated the hamlets and villages, which were at last to fall into the clutches of the expanding city, and lose their distinctness. When this century closes, it will look upon a very different London from that in which our great grandsires lived content when it opened.

Peter Cunningham, describing the London of 1848, the year when the *Journal of Horticulture* came into existence, remarked that the rents of the metropolis had been gradually advancing since 1800, and, while that was the case, building would go on rapidly, nor was it likely to stop until rents began to fall. At this hour, though we notice some local fluctuations, there is no sign of a general reduction, yet the great rise of all rates must tend at last to produce this result. But the grand impetus to building operations which has produced such changes in London suburbs had not been given when Cunningham wrote. The nurserymen and market gardeners seemed likely then to hold, for a good while, possession of grounds which yielded during

average years a very good return upon the capital invested. We have no statistics giving positive information, but I believe, fifty years ago, the bulk of the vegetables consumed in the metropolis were raised in Middlesex, Surrey, and Essex, and a great part of the English-grown fruit came from orchards within the sound of St. Paul's. It was curious to notice, as the rural districts near London became the sphere of building operations, that the market gardens were generally the first to be cut up into streets and roads; the private residences, with park-like grounds, scattered amongst them, held out longer, but they, too, succumbed at last.

At the census taken four years after the Queen's accession the population of London was about two millions, at the next in 1851, a quarter of a million had been added, but the advance during the last forty years has been much greater. The Great Exhibition of that year was a turning-point in the history of the metropolis, bringing, as it did, visitors from all countries, and it added to the number of residents. Then the rapid increase of periodicals and magazines, in which London localities or London life were frequent themes, tended to draw people to the metropolis as a grand centre of wealth and activity. Again, the increase of railway lines and branches opened up new facilities for reaching London from many places, where, in Georgian times, most of the inhabitants seldom travelled any distance. Probably people would have been less eager to migrate to London half a century ago had the insanitary condition of many districts then been revealed, but the newspapers of that time took little notice of matters which would now be soon subjected to a searching investigation. Even the prevalence of the fatal cholera in more than one season did not scare people, though during the autumn of 1849 the deaths in the limited area of London of that date amounted repeatedly to 300 a day, or more, from that disease alone. During some of the cholera visitations the trade in fruit and vegetables suffered considerably, owing to a notion that even persons in health should abstain from these to lessen the risk of taking the epidemic. Curious to say, an investigation of the callings of those dying from cholera in one suburban neighbourhood showed that gardeners were more exempt than other men. Large crops were raised in many of the market gardens, largely with the aid of animal manure, and the method of rapid rotation of crops was general. Therefore it is not at all astonishing that when in low-lying districts houses were erected upon ground which had been thus treated for years, built without any substantial foundation of brick or concrete, they turned out to be nurseries of malaria.

Just about the time this Journal entered on its honourable and useful existence I lived in a house not far from Buckingham Palace, on the border of Westminster. This was not very lofty, yet from its upper windows could be seen the hills of Surrey—i.e., Lavender Hill, Pig Hill (so called formerly), and others between Battersea and Clapham. Up to that date the builders had not been very busy on the Surrey side of the Thames, and even to this hour the southern suburbs of London seem endeavouring to retain somewhat of a semi-rural aspect. In 1848 there were still open hills on the Middlesex side within the boundaries of Westminster which gave a free view across fields where the sportsman could shoot wild fowl. Then the Willow Walk not only retained its name, but its Willows and rivulets ran amongst the market gardens, over which persons had to cross by a plank bridge. The broad space, however, which bore the name of Tothill or Toothill Fields had been built over before the Queen's accession; all but the green centre of Vincent Square, which yet remains as a memory of a spot where the old herbalists sought medicinal plants, and the ditches afforded Watercresses to the Westminster folk.

But for the obstruction caused by the warehouses and other buildings of Lambeth persons could have seen, by aid of a glass, from the terrace of the Houses of Parliament, the orchards which fifty years ago yielded crops of fruit about Vauxhall and Kennington, in spite of the London smoke. More recently, about seven years since, I was shown Mulberries, Cherries, and Pears taken from a small garden at Vauxhall, which was being cleared to be thrown into a recreation ground then forming. In 1848 I believe there was yet visible a remnant of the stream called the Effra, which flowed from the uplands of Brixton and Norwood to South Lambeth, a boon to many gardens near which it passed, but in its capricious moods apt to damage some of them by a sudden overflow. It was in that year, on April 10th, that Kennington Common, a wild, unattractive space of waste land, was the chosen place for a vast Chartist gathering, which caused no small alarm at the time. People thought that Fergus O'Connor and his companions were going to inaugurate a revolution, but the movement ended in an ignominious collapse. What a contrast between the scene of that day and that which greets us in the present Kennington Park, a home of flowers from spring to autumn, where the trees and shrubs planted since the old common underwent transformation have made good progress, and it affords a pleasant resting-place amid the bustle of a suburb traversed by many thousands daily!

Taking another retrospect, in that neighbourhood there was, fifty years since, a remnant yet of the far-famed Vauxhall Gardens, a favourite resort for nearly two centuries. Diminished by various changes, with little left of the garden about it, about 1852 it was closed, and the ground cleared for building. Some of the old trees remained till the last, but the Gooseberry hedges, the Asparagus grounds, the beds of Roses (for it was at one time partly a nursery garden) had vanished with the nightingales, long before that date. Many persons now living will remember the Surrey Zoological Gardens, which occupied a space of about 12 acres at the time of which I am writing, situated between Kennington and Walworth. Though thus named in the later years of its history, at first it was a sort of botanical gardens, which, opened to the public during the reign of William IV., was planted with a variety of exotics. Lectures were given, open air demonstrations in botany, and so forth, but the educational scheme did not answer, and so Mr. Cross removed his animals thither from Exeter Change, zoology and miscellaneous exhibits becoming the attractions of the place. It had a rather extensive lake, used for aquatic shows. At one time there was a probability the gardens would be taken by the Royal Horticultural Society, when a suburban site was being sought for a show garden; had that happened the ground might awhile have escaped the builder.—J. R. S. C.

WANTON WASTE OF WEALTH.

THIS alliterative heading is taken from some significant remarks by Mr. Roupell in his paper on "Suburban Fruit Growing," in part 3, vol. xxii., of the Journal of the Royal Horticultural Society, just published. The following are the remarks alluded to:—

"Fruit growing in the suburbs of London is no new thing. From time immemorial market gardeners have grown their fruit and vegetables, and taken them to market, bringing back in their carts and vans manure obtained at a cheap rate in the town. The distances to be covered fifty years ago were comparatively small, and growers made a pleasant and comfortable living by the cultivation and sale of Grapes, Plums, Apples, and bush fruit, in addition to vegetables, all of which brought good prices. The land was not over-drained, and in some cases it was marshy and waterlogged. Ponds and ditches were in many instances the sources of their water supply for horticultural purposes; but in those days we did not suffer so much in dry weather from lack of moisture as we do now that there is no reserve stored up in the subsoil.

"The main drainage of London, though necessary from a sanitary point of view, has greatly lessened the fertility of the soil. In the first place, it has carried to the sea incalculable wealth in the shape of organic matter, which was formerly available for the fertilisation of the land. Houses were then drained into cesspools; the night-waggon was a familiar institution in the town; hardy farm labourers cheerfully engaged in the most offensive tasks for the sake of a little addition to their wages and privileges; and Mother Earth, the great deodoriser, received back her due. But now she is robbed and starved, or cheated with stable litter, which differs greatly from the old farmyard manure, or she is insufficiently fed with artificial manures, some of which are of but little value.

"In the second place, the main drainage of London has intercepted all the springs and rivulets which previously found their way from the beautiful hills which surround London to the valley of the Thames, and the blessed raindrops which heaven distils are bound by Act of Parliament to hurry from the roofs of palaces and cottages alike through the same foul pipes which carry the diluted sewage to the sea. It is within my knowledge and recollection that the eminent engineer Robert Stevenson the younger, and others, who professionally approved the main drainage scheme, regarded it as a necessary first step which would eventually have to be followed by a system of separation. This is not a cheerful prospect for the ratepayer, but the question will have to be faced, as Nature will inevitably call the inhabitants of London to a strict account for their wanton waste of the vast wealth of organic matter which is now sent down to the river's mouth to feed or poison the fishes.

"One has only to look at the standard trees in the suburban gardens to see how rapidly they are failing. The tops are dying—an ominous sign. And this is true also of the forest trees in Kensington Gardens and some of the public parks, especially where the subsoil is gravel.

"I have touched upon this branch of the subject because one of the first necessities in fruit growing is a copious supply of water. My friends often ask why their out-of-door Peaches fall off every year when they are about the size of hazel nuts, and on examination at the foot of the wall the subsoil is always found to be as dry and hard as bath brick.

"When the old suburban gardens were first laid out the soil was generally fresh and in good condition; for as building extended meadows

and market gardens were absorbed, and fruit trees thrive in the freshly broken ground enclosed within the garden walls; but of late years the speculative builder has converted the light soil into mortar for building purposes, and the new gardens consist generally of clay and rubbish fenced in with oak palings. The fine old gardens of Dulwich, Tulse Hill, Streatham, Putney, and other suburbs still remain, but the surface soil is generally exhausted, sour, and full of fungoid germs. To buy fresh soil in quantity would now be an enormous expense, and the question is, What should be done to restore fertility to the soil?

"I am afraid that the art of trenching is in danger of being lost in the suburbs of London. Nearly all young gardeners want to get into the glass houses and amongst the flower pots. The first tool put into the hands of a young gardener should be a spade, and if he do not begin to use it in early years he will never have the muscles or the inclination to use it manfully. If you want trenching done properly you must look about for some old labourers to do it. Of course a good deal depends upon the subsoil, and I do not advocate the bringing up to the surface a quantity of gravel or stiff clay. But a portion of the latter material may with advantage be turned up, and when dressed with lime and exposed to the frost it will soon break down and admit of being incorporated with the rest of the soil. Where it can be done some clay should be burnt or charred and worked in with the rest. All lime and brick rubble should be saved. The ashes of rubbish heaps, soot, sweepings of the poultry yard, dovecote, and stable, refuse from the kitchen, weeds, and leaves should be collected and spread over the ground to be turned into the bottom of the trench, so as to be buried with the stale and exhausted soil from the surface.

"When the trenching is completed the surface should be heavily dressed with quicklime and be left rough for the winter. In the following spring a liberal dressing of quarter-inch bones or coarse bonemeal should be lightly forked in and a green crop, say of Tares, raised, which might with advantage be dug in to freshen and enrich the soil. The land would then be fit for planting with fruit trees in the following autumn. Stable litter—I will not call it manure—is of but little value except as a mulch in dry or frosty weather. This should be spread round the trees after planting, and when there is a good crop a surface dressing of any good manure, consisting mainly of phosphates and potash rather than nitrates, should be sown. The trees will require to be watered in dry, hot weather, as the roots, if planted properly, are near the surface.

"I have tried planting maiden trees, but whether pruned the first year or the second, I have never been able to make such good bushes or pyramids as those obtained from the nurseries under the description of 'Two-year-olds, with some fruit spurs.'

"With respect to pruning it has been humorously said that 'there are two sets of fools—those who prune too much and those who don't prune at all.' I have found it better to be cautious in the use of the pruning-knife after the foundation of the tree has been laid, and to confine pruning to thinning out objectionable shoots rather than to shortening them back. Summer is to be preferred to winter pruning, as the wounds heal over more quickly and leave less opportunity to canker germs and American blight to effect a lodgment.

"Summer pinching has its uses, but bushes pinched into stunted growth can never be got out of it. I prefer a more natural system."

There are several excellent essays in the publication in addition to that from which we have taken the above notes. These comprise "Garden Peas," by Mr. N. N. Sherwood, V.M.H.; "Origin of Species—Inducing Varieties," by the Rev. Professor G. Henslow, M.A., V.M.H.; "Economic Uses of Bamboos," by Mr. A. B. Freeman Mitford, C.B.; "Hybrid Water Lilies," by Mons. Robert Latour Marliac; "Water Lilies," by Mr. Jas. Hudson, V.M.H.; "Perpetual Strawberries," by Mons. Henri de Vilmorin, F.R.H.S.; and "Disa grandiflora," by Mr. F. W. Birkinshaw.

COMMENTS ON APPLES.

MR. PICKER has taken my criticisms very well on the whole, but I wish he had left out the last sentence. He must not forget that he specially invited criticism. As to Bramley's Seedling, the difficulty appears to be that it takes up too much room. This also seems to be the objection taken to it by a writer in the previous number of the Journal (which is unfortunately mislaid, so that I have forgotten his signature). He grafted Bramley's, and it grew luxuriantly for two years, and then he root-pruned it! A two-year-old graft! Bramley is not a toy or a pocket Apple tree, but a fine big tree, to produce Apples by the sackful, and it should not be planted or grafted where there is not room for it.

I hoped I had a little claim to the grand old title of gardener; but, anyhow, it is a piece of news to me that it is not the gardener, nor yet the unfortunate folk who have to eat the produce, but the "practical cook"

who decides upon what varieties are to be grown. I know it is the general idea—traditional with cooks who do not have to eat it, but general ideas are not always right—that Apple sauce should be acid. I like sweet Apples for sauce; acidity gives me the gout or bad temper or something. Somebody wrote, he supposed I did not like to eat sugar with my Apples. Well, I do not, when I can get the sugar, naturally provided and properly mixed, in the Apples themselves.

Mr. Picker writes of a gardener carrying in Lane's Prince Albert for dessert, who said they were appreciated "as a change." If that gardener's employer likes a change from best to worse for the sake of change, I can only say I do not agree with him. My "fixed taste" is that "the best of everything is good enough for me."

Mr. Picker makes a point when he says that he cannot understand how I can grow Cox's Orange when my soil is not good enough for Gascoyne's Seedling. Well, I cannot grow Cox's Orange to size and perfection without a great deal of trouble, but I must have it if I can possibly manage it, as I have nothing to take its place, whereas I can find a substitute for Gascoyne's Seedling. By using all means of strong and suitable stocks and high feeding I can get Cox's Orange to grow well and to fruit freely for my own consumption, but not to produce samples fit to compete with those grown on better land. I have not succeeded so well with Ribston Pippin, and anyhow I should prefer the other.

Yes, I do go to church. I have never heard anyone find fault with me in that respect. As to sermons, I am so unfortunately situated that I always have to listen to the same man. Yes, I am getting rather tired of him. His sermons are not "very good," and I am afraid others would object to the "same two every week for eight or nine months," even if I did not. In short, I am still of opinion that too many varieties of Apples are grown as a rule, but I know it is a good test of the energy of a gardener, whether he will have the pluck, gradually, perhaps, but surely, to do away with everything—even "useful" varieties—and grow only what he finds to be the best in his own garden.—W. R. RAILLEN.

APPLES IN IRELAND.

I HAVE read Mr. Burdley's letter on page 434, December 8th last, and have to thank him for his appreciative remarks. I regret much I was not at home when he called to see my humble efforts at fruit farming. I am greatly pleased to know that so good an authority was well pleased with what he saw. He asks how I got the idea of growing Bramley's Seedling, and when I give my reason it will also be a reply to your correspondent "K., Dublin," who speaks of wholesale failures in Ireland where Apple growing has been tried.

My idea of growing Bramley's so largely came in this way. I visited a number of gardens in the district where the soil was similar to mine, and found most of the leading varieties of Apples in them. Some were a partial success, others utter failures; I only found Bramley's in two gardens. It was a great success in both; I therefore concluded that it would be a waste of time and money to plant anything else on a large scale. I began with one hundred young trees, and grafted my old trees from them.

Another view led me to grow this variety. It is late, and the fruit keeps well. If I had early Apples, such as Lord Suffield or Ecklinville, good as they undoubtedly are, I could not sell them for half the money Bramley's would realise, because most of the orchards in Ireland are early, and the market is glutted in October. If Apples are cheap then, I can hold mine over till Christmas, or even till April, when I am sure of a good price. In March, American Apples are over. Bramley's is then in perfection, and the crops sell at good prices. Our cold, damp climate, I believe, suits late varieties. Foreign Apples (Australian excepted) are of little value in March. We can compete with them for late Apples, but we have not sun enough to equal them in the early varieties.

I did not go in for Bramley's alone; I tried Lane's Prince Albert, Stirling Castle, Devonshire Quarrenden, Lord Suffield, Worcester Pearmain, Ecklinville, King of the Pippins, Cox's Orange and Ribston Pippins, Blenheim Pippin, Grenadier, and Duchess of Oldenburg. I find Ribston does better than the Cox's Orange or King as standards, but all need a wall. Blenheim will not do at all here as a standard, but succeeds fairly well as cordons against walls. I only tried from two to six trees of each variety, in order to find those which would suit the land, and as soon as I found a variety would not answer I grafted it with Bramley's, because it proved suitable. I believe in increasing those that will flourish, and clearing out all that will not. I do not like to see things in a failing state, and have no time to try to induce them to grow.

I think if those growers "K., Dublin," writes of had begun in a proper way by testing their land with a number of varieties, they would find at the end of three years that a few would answer, and instead of planting (a collection) 500, had several trees of the few which succeeded, they would not have failed.—J. S. SMITH, *Oaklands, Boyle*.

WEATHER IN LONDON.—Thursday and Friday of the last week of 1898 were fine, dry, and cold; but Saturday was wet in the morning, drier in the afternoon, followed by a soaking evening. Each day was somewhat cold, but not really seasonable. The New Year was ushered in by a dense white fog, which clearing was succeeded in the evening by heavy rain. On Monday morning there was a heavy downpour of snow and rain, and towards evening the wind became almost a gale, and was accompanied by driving rain. Tuesday and Wednesday were dull and warm.

TREES IN RICHMOND PARK.—Much adverse comment has been created by the action of the Richmond Park authorities in marking for destruction an immense number of fine trees growing in the woodlands skirting the walks near the walls towards the Kingston end of the Royal demesne. The opinion is strongly entertained that the removal of the many hundreds of trees selected is quite unnecessary, and that if carried out the appearance of the park will be considerably marred. H.R.H. the Duke of Cambridge, appealed to as ranger of the park, has replied that only such trees are to be removed as are necessary to insure room for the proper growth of the remainder.

THE LATE MR. THOMAS SHINGLES.—Many gardeners will hear with regret of the death on the 27th ult., after an attack of apoplexy, of Mr. Thomas Shingles, who had been head gardener for the past twenty-three years at Tortworth (Lord Dueic's beautiful seat in Gloucestershire). As is well known, Tortworth is noted for its splendid collection of hardy trees and Conifers. It was the writer's privilege to visit him occasionally, and what a treat it was to ramble through the arboretum with such a guide. He was a quiet unassuming man, but few men were better versed in the nomenclature of trees and shrubs. One who knew him well says, "There never was a more just master, a kinder or truer friend, or one more ready to help anyone who was trying to do his duty."—S., Yorks.

IMPERIAL PENNY POSTAGE.—Many of our readers will have relatives and friends abroad, and they will probably be glad to know exactly to what places the new rate will apply. The postage will be 1d. per $\frac{1}{2}$ oz., instead of 2 $\frac{1}{2}$ d. as before. Aden, Ascension, Bahamas, Barbados, Bermuda, British Central Africa, British East Africa, British Guiana, British Honduras, Canada, Ceylon, Cyprus, Falkland Islands, Fiji Islands, Gambia, Gibraltar, Gold Coast Colony, Hong Kong, India, Johore, Lagos, Leeward Islands, viz., Antigua, St. Kitts, Nevis, Dominica; Montserrat and the Virgin Islands, Malay States (federated), viz., Perak, Selangor, Negri Sembila, and Pahang; Natal, Newfoundland, Niger Coast Protectorate, Niger Territory, St. Helena, Sarawak, Seychelles, Sierra Leone, Straits Settlements, Tobago, Trinidad, Turks Islands, Uganda, Windward Islands, viz., Grenada, St. Lucia, and St. Vincent.

ANOTHER ONION.—Yet another addition to our swollen lists of Onions is announced; and this time it is a regular "Aristocrat." Not, I hope, a "bloated" one, but one of slim, genteel figure, depending more upon its high flavour and intrinsic merit of flesh than upon huge, watery dimensions. I fear all the same we shall see our Aristocrat friend dressed up in aldermanic clothes by-and-by, having been fattened up to fit them by large doses of turtle soup manures that have the merit of producing bloated earcases in Onions in particular, and in most things in general. But I am always puzzled when I hear of a new Onion to understand where the distinction comes in that makes it differ from others; not a few so-called established varieties will give several forms to the bulbs. We saw ample evidence of that in the great trial conducted last autumn at Chiswick, and the variety that produces every bulb absolutely true to character does not exist. I should like to see each so-called variety very clearly described, and its true features distinctly delineated, so that each one may be in that way detected. Now there is practically no distinction in the plant leafage. This is, as a rule, alike in nearly all cases. It is not until the bulb is fully formed that distinctions are evident, and then we see some globe-shaped, nearly all exactly alike, others round, others flat. Some have white skins, one or two red ones, but the majority are of pale or yellowish brown, and there the distinctions end. I hope the new Aristocrat is an unmistakable swell, disdaining to have any connection in appearance or character with the ordinary Craigs, Exhibitions Excelsiors, Wroxtons, Main Crop, and other swollen democrats.—A. D.

ROYAL HORTICULTURAL SOCIETY.—The first meeting of the Royal Horticultural Society in 1899 will be held, as usual, in the Drill Hall, James Street, Westminster, 1 to 4 P.M., on Tuesday, January 10th.

GARDENING APPOINTMENT.—Mr. H. E. Kennedy, late of Halton Estate, has been appointed head gardener and steward to Sir Alfred West, Bart., Kileroney, Bray, near Dublin.

PRESENTATION.—Mr. George Wall, for the past twelve years head gardener to W. S. Gilbert, Esq., Grims Dyke, Harrow Weald, was the recipient last week of a handsome silver inkstand, presented by the garden staff, on the occasion of his resigning the charge of the gardens at Grims Dyke. Mr. Wall carries with him from the neighbourhood the best wishes of a large circle of friends.

"FLORILEGIUM HAARLEMENSE."—No. 8 of this interesting and valuable work is now before us, and for excellence of production is quite equal to its predecessors. As is customary, the plates are three in number, and comprise Hyacinth Mont Blanc, a well known and largely grown single white variety; Tulips Joost Van Vondel and White Van Vondel, the latter of which is particularly praiseworthy; and Spanish Irises Blanche Superbe, Chrysolora, Sappho, and Coquette des Blanches. The tones of colour in the Iris flowers are beautifully reproduced. As we have previously stated, the publisher is De Erveux Loosjes, Haarlem, Holland.

GESNERAS.—These attractive plants appear to have been somewhat neglected of late years, although few make such a show during the winter months. When at Theobalds, Hawkhurst, recently, I noticed a good stock in an intermediate house, where the plants looked handsome interspersed with Ferns and Palms, the flowers being produced in the greatest profusion. Mr. Masters, the gardener, always grows Gesneras well, and does not consider them difficult to manage; in fact, he treats them very much the same as Achimenes. It is necessary to add, however, that they must be carefully watered and not syringed. Two of the best varieties are *G. zebrina* and *G. exoniensis*.—J. G.

ARTIFICIAL MANURES FOR POTATOES.—In an experiment carried out during the past season at the University College, Nottingham, the best result in the manuring of Potatoes was obtained from a dressing of 6 cwt. superphosphate and 4 cwt. nitrate of soda. This mixture cost £2 6s. 6d., and it gave a net increase of £3 10s. 6d. in the value of the tubers grown with it, as compared with the produce of the plot which had no artificials. As showing, says a contemporary, how puzzlingly variable the results obtained with different combinations of the same manures on the same land sometimes prove, however, it is worthy of note that on another part of the field on which these experiments were being conducted 6 cwt. of superphosphate and 2 cwt. nitrate of soda—at a cost of £1 10s.—gave, not a gain, but a loss of 6s. 5d. per acre.

MR. BARR IN CANADA.—We take the following "editorial" from the "Ottawa Citizen" of December 22nd, 1898:—"Mr. Peter Barr, a prominent horticulturist, of London, England, who is visiting Ottawa, makes a suggestion that is well worth the attention of the Government. It is the establishment of a School of Forestry for the instruction in the propagation and conserving of the forests. Much attention is being directed to this branch throughout the British Empire, especially in India, where it is a well-organised departmental work, the country being divided into districts under foresters and rangers. It appears there is no School of Forestry in the British dominions, and Mr. Barr thinks that the Imperial authorities would make a grant for the support of such an institution where thorough instruction could be imparted in the growth, care, and preservation of timber, and that Ottawa is just the place for its location."

OUR JOURNAL.—I think the contribution by "An Old Provincial" (page 490) will find an echo in the minds of many readers. Those who have the opportunity of comparison know that the Journal provides its readers with pleasurable entertainment, as well as useful information based on practical experience. I, in common with hosts of others, feel grateful for the literary fare supplied, which is so appetising and invigorating. It is beyond many good essayists to impart a sense of humour in the practical teaching, and certainly it is not necessary often, but a change in the "fare," such as "An Old Provincial," or a Mr. "W. Pea" can furnish, certainly intensifies the interest of the ever-welcomed Thursday reading. Many persons, I feel sure, will agree with "An Old Provincial" in admitting that "our Journal" has done an immense service to the cause of horticulture by these genial, instructive discussions, that have largely helped to make it the undoubtedly popular paper with gardeners that it is to-day.—WILTS.

— **MANOR HOUSE, EALING.**—At a meeting of the Ealing Urban District Council it was resolved to accept the offer of Sir Spencer Walpole to sell to the Council, for the purposes of a public park, the Manor House estate. The estate comprises a mansion, at present occupied by Miss Perceval, with grounds attached covering about 31 acres, the purchase price of which is £40,000. The sale is subject to the life interest of Miss Perceval, and the Council will not obtain possession till that lady's death.

— **THE FOREST OF DEAN.**—The foresters of Dean are about to enclose the whole of the 11,000 acres which belong to the Crown, for it has been decided to restore the natural aspect of the forest by planting Beech and Oak extensively, with Larch, Chestnut, Sycamores, and other trees. This treatment has been recommended, says a contemporary, by Mr. Hill, conservator of Indian forests, and, as a result of its application, it is hoped that the fine Oak timber which used to be the feature of this forest may again be seen. An invitation has been extended to all of those interested in the practical management of the woods to visit the place and note the working out of the scheme.

— **JANUARY WEATHER.**—We have had, on the whole, a remarkably fine Christmas so far as weather is concerned, but if Mr. Clements' forecast is anything like accurate we shall soon have a change. January generally, he says, will be a cold month, and about the 22nd and 29th there will be "drifting snowstorms." There will also be rain or snow on the 3rd or 4th and round the 7th and 9th. Indeed, the first and last nine or ten days of the month will be of a "generally unsettled character." We have learned, however, not to place much reliance on Mr. Prophet Clements.

— **DECEMBER WEATHER AT HODSOCK PRIORY.**—Mean temperature, 44.2°; maximum in the screen 58.6° on the 5th; minimum in screen 24.3° on the 31st; minimum on the grass 13.1° on the 31st. Number of frosts in the shade nine, on the grass eighteen. Sunshine twenty-five hours, or 11 per cent. of the possible duration; difference from average, eight. Rainfall, 2.00; difference from average 0.10; rainy days, thirteen; maximum fall, 0.48 on the 26th. Rainfall from January 1st 20.87 inches; difference from average 4.41. Mean temperature 3° higher than any of the previous seventeen years. Very little rain fell till the last few days.—J. MALLENDER.

— **SUSSEX RAINFALL.**—The total rainfall at Stonehurst, Ardingly, for December was 2.86 inches, being 0.12 inch above the average; the heaviest fall was 0.62 inch on the 27th. Rain fell on sixteen days. The total fall for the year was 23.98 inches, which is 6.02 short of the average. It has been the driest year in a nineteen years record. The nearest approach to it was that of 1884, when the amount was 24.05 inches. The maximum temperature was 54° on the 5th and 11th; the minimum 25° on the 31st. Mean maximum, 47.12°; mean minimum, 38.09°; mean temperature, 43.10°, which is 4.96° above the average. So far we have had a green winter, and December has been much too mild. Early blooming Pears are swelling their buds too fast, and green crops are growing, and but poorly prepared for a hard frost.—R. I.

— **WINTER TREES AT HACKWOOD PARK.**—Although at no period of the year do fine trees wear so noble an aspect as when in summer clothed with luxuriant leafage, yet have they very attractive charms when seen in the winter without a leaf, and when on a bright, clear day the stems and branch sprays stand out against the sky in illimitable and beautiful tracery. Poor must be the soul of the observer who does not find in such a sight much to arouse his higher senses, and to appeal to his admiration of Nature's handiwork in but one of her many forms. There are thousands of noble trees at Hackwood Park, both on the verdure and in that huge enclosure known as the Spring Woods. One sees magnificent Oak, Elm, Beech (some of these with clean stems, as masts have, 60 feet high), Silver Spruce, common Spruce, Larch, Sweet Chestnuts, Ash, Lime, Sycamore, all of the finest description, and whether a huge giant standing alone, whether, as in these woods, somewhat densely, or whether in noble groups in the park, trees constitute a really grand feature. What marvellous difference to any extensive area of land is made by the presence of trees, especially of such trees as this grand Hampshire park is producing! It is interesting to see specially, as I occasionally like to do, the giant Beech in one part of the park, at once the finest and noblest I have ever seen. Near to it is an aged Oak, on a branch of which is growing a cluster of Mistletoe; indeed, here in the park may that parasite be seen on Elm, Lime, Thorn, and Apple, also an unusual combination. How clean and robust is the Beech on the chalk formation! just as in the lower soils where loam abounds Oak is very fine and healthy. The Park is for its trees a happy hunting ground for artists.—WANDERER.

— **MR. BRISCOE-IRONSIDE IN ITALY.**—We are informed that Mr. Briscoe-Ironside has recently concluded arrangements with an Italian to found a business establishment in the north of Italy for the purpose of extending the cultivation of the Chrysanthemum in that country. Preparations are being made to start on an extensive scale, and the new undertaking will be the first of its kind. The firm will be known as Messrs. Stroppa and Briscoe-Ironside, Tradate, Lombardy, Italy.

— **THE DECLINE OF COFFEE DRINKING.**—Although some medical authorities assert that Coffee is an antiseptic and disinfectant and effective in cases of typhoid, the general consumption of the berry in England does not increase. It will be seen from a reference to the Customs' returns that Coffee is still on the decline. This is due no doubt to the ease with which Tea can be brewed by comparison, and the tremendous spurt made of late years by the wealthy firms engaged in pushing the sale of Tea. Coffee is left to struggle on and live on its ancient reputation—a reputation, by the way, held in affectionate regard by steady-going Coffee drinkers, who resist all efforts to wean them from their beloved beverage.

— **"THE HORTICULTURAL DIRECTORY."**—As has already been announced, this long familiar annual is now being issued from 12, Mitre Court Chambers. Besides registering many more gardening establishments and gardeners' addresses than before, also publishing an extended list of nurserymen, seedsmen, and florists in this and other countries, as well as of horticultural builders, engineers, and sundriesmen, landscape gardeners and park superintendents, much miscellaneous information is given in the 550 pages, including a descriptive register of the plants, flowers, fruits, and vegetables which have been honoured by the Royal Horticultural Society from the end of September, 1897, to the close of the corresponding month in 1898. The present is the fortieth issue of the Directory, and the price remains as before—one shilling. It is alike suitable for the tradesman's desk and the gardener's table—handy for reference all the year round.

— **DEPTH TO PLANT FRUIT TREES.**—Some time ago the "Agricultural Gazette" obtained the views of three eminent nurserymen upon the depth at which to plant fruit trees. Two recommended planting so that the budding mark would be about 2 inches below the surface of the soil, to hide the scar, and keep it from injury, while the third maintained that the trees should be planted at the same depth as they had stood in the nursery in which they were raised. The last objected that an Apple on the Paradise stock, for example, would lose the advantage of the dwarf habit of the stock if the scion were placed below the surface of the soil, and thus were allowed to throw out roots. To this the reply was that a scion will not throw out roots in one out of a hundred cases. A fourth authority confirms this statement. There is, however, a further objection to the slight extra depth in planting—namely, that it is desirable to keep the roots as near the surface as possible. Thus the relative advantages of the two methods are puzzling, and experiments to decide on the question might well be carried out.—("Irish Farmers' Gazette.")

— **GIFT PLANTS AT CHISWICK.**—The very large increase found annually in the fellowship of the Royal Horticultural Society doubtless finds some stimulus in the somewhat liberal distribution of plants free of cost which is made annually to these Fellows from Chiswick. Very much of the labour expended there is connected with the propagation and growth of these plants, for all are in pots, and just now long ranges of pits may be seen full of hardy plants, especially alpine, for there is in them quite a remarkable collection of Saxifrages, Sempervivums, Primulaceæ, and similar plants, running evidently into several thousands, and whilst in small pots yet of each kind quite perfect samples, such as any nurseryman might be proud to send out to his customers. In other directions are collections of herbaceous and American plants, whilst in the houses great quantities of Palms, Ferns, Dracenas, Crotons, and other desirable plants are being pushed on for distribution. Certainly guinea Fellows can, what with privileges, journals, and plants, get back something like 150 per cent. for their outlay. I wonder how far distributions of this kind affect legitimate trade, whether at all, in fact. Probably the thousands of plants that go out from Chiswick are, after all, but as a drop in the ocean; perhaps they do but serve to whet the appetite for more, which have to be purchased. Certainly, the R.H.S. does so much for the popularisation of horticulture that the trade have little room for complaint. Fellows not animated by the lower instinct of the general, and who would prefer to see Chiswick devoted absolutely to the highest interests of horticulture, may growl over that somewhat mean use to which the gardens are put, but human nature is still and ever will be of the sort that prefers its pound of flesh to the public good.—A.

THE "ROSARIANS' YEAR BOOK."

(Continued from page 56, last vol.)

There is no denying vegetation matter, as well as manures, not only give great protection to the roots of dwarf Roses, but act as insulators to the same roots. Dry leaves and other litter are almost useless at the time their protection is most needed—viz., during the prevalence of a frost-laden wind. Nor is it any great trouble to draw up some of the surrounding soil around the base of dwarf plants. I have not and will not dig my eyes under these conditions, nor have I experienced it under winter is experienced through the winter. I have, however, I would always earth up dwarf plants. Even if all the upper soil should be washed away, the lower and covered eyes will come up in spring, and generally produce a good plant again during the next summer. This is especially the case with dwarf Teas, Bourbons, Indicas, and Polyanthas.

But when we come to Roses grown in standard or half standard form, it is more difficult to protect. This is unfortunate, as they are the most exposed, and have no eyes at the base to take place of lost growth. A lattice hedge Rose is hardly enough, but its natural character of growing ranker is checked under culture as a Rose bush, and the apex of the stem is fully exposed. In the cases and positions the case is quite different. Wind is the chief enemy of Roses in general, and not around the collar in the case of dwarfs, especially when accompanied by severe frost. A little larchen, straw, or other light litter can be shaken among the branches, but unless we draw these together slightly the protecting material will be blown away. A slight shower will also wash it down to the roots, where it will be of no use, as the roots of our native hibernia are perfectly hardy.

Large and bushy plants should never be planted with any last varieties and not be stand perspective bad weather, according to aspect and aspect. Here we can scarcely protect without much labour and expense, and a variety not suitable to the aspect is used, other elements of the year will also be too inclement.

There is a second reason for protection upon walls with a due south aspect. It will appear strange to some, but I am fully convinced that bright sunshine is equally as harmful in such a position as the sharpest frost. How often we experience a few weeks of sharp frost, a quiet atmosphere, and bright sunshine day by day. At night the frost would be frozen to several degrees, but by mid-day it is thawed, only to be frozen again two or three hours later. This alternate freezing and thawing does far more harm than if even colder weather was experienced, and the Rose would not be protected to so many and sudden changes. I would prefer to have a mild or warm sitting against the wall at mid-day, and so partly counteract the effects of bright sunshine. At the same time this would be a help against night frost, and might be left on night and day, so long as one did not mind the unsightliness. There are few more disappointing places in Rose culture than to lose the long growth of our tender children during winter.

In almost all instances it is the long rods of the previous summer's growth that yield that glorious display of blossom early in the season, and I think we may say this is the case without exception among the tender varieties. I allude to such as Lamarque, Merveille d'Eté, climbing forms of Devonshire, Hiphotea, and Paul de Serres, white and yellow Portlandia, Cloth of Gold (if you can save the wood), Laune Desprez, Madame Dupont Verdet (Pier), and Hattatere. Among the tender dwarf or bushy grown are Chant, Celestial, Chiquette, Comtesse de Nubling, Comtesse de Paris, Josephine Milla, La Grandeur, Lucarne Godeau, Madame Walshe, Monna Phylade, Mrs. James Wilson, Refuse de Portugal, Primrose Dame, and Hattatere.

In the Rose garden are still have many very showy hips and berries, and these alone make a bright display. Many Hybrid Sweet Briar are strongly marked with berries. Lord Penrhyn has numerous kinds of small and almost round fruit, while Jeanne D'Arc and a few more have long and large berries carried boldly upon stems from 1 to 3 feet in length. Out and amongst among almost any flowers or foliage, or dried Chamon, these berries are very showy and lasting. My own experience is that birds do not attack the Rose berries nearly so much as with much acidity elsewhere. Most of the Rugosa are eaten early in the season, but calocarpa still carries large trusses of deep red fruit.

For the two last Christmas seasons we have had grand spikes of the Hybrid Sweet Briar variety, which, with a few sprays of Viburnum or Ivy, had a very showy effect. Myrica peruviana has long long red hips, while others remind the French Rose in growth, and has

almost pure black berries. Gymnocarpa has yellow hips of curious form; placarpha has very small pea-shaped hips of a red colour, and panicata supplies very large scarlet fruits. Rose-apples is a newer variety with large deep crimson and almost maroon coloured berries. A. PIER, Uckfield.

THE "ROSARIANS' YEAR BOOK."

THE active veteran and indefatigable worker in the floricultural domain—Rev. H. H. D'Ombrian—has had sent to us the twentieth issue of his welcome annual, with its neat emblematical cover, the "Rosarians' Year Book." We do not know that we could say anything better and truer of it than that it will rank worthily with its several predecessors. It is like, yet unlike, them all—like them in garb and good feeling; unlike them, of course, in the matter. Not that it is more pleasantly readable than its predecessors, but equally interesting, while not less substantial.

Mr. R. Harkness has the "pride of place" in the present issue, and the photograph of this still youthful but professionally experienced and successful rosarian is excellent. The history of the rise and progress of the Brothers Harkness is succinctly narrated by the editor, and their remarkable achievements in the arena recorded. A well deserved tribute is paid to the unassuming manner of Mr. Harkness in these words, "He never boasts of what he has done, and he never falls into the grievous error of attributing his ill-success at any time to any but the right cause—the superiority of the Roses staged against him." If this were the rule at all exhibitions the meetings would be the more pleasant, and especially perhaps to those taken by surprise and disappointed by the verdicts. In this matter, however, improvement is general, and the great bulk of exhibitors display the truest manhood in bearing their temporary misfortunes bravely.

The Rev. A. Foster Melliar contributes some "Recollections of Roses and Rose-showing." In the "good old days"—i.e., when there was no one from Colechester against him—it seems this then lucky grower and exhibitor could buy a pony and trap or a Guernsey cow with his prize money. He does not say so, but it is not difficult to infer that he could win almost anything he wanted if there were no Cants, Lindsells, or Pembertons. But we must pause and guard against a rap on the knuckles by saying that the owner of the "Rose" cow has turned the tables against all these celebrities, and must therefore have been not "lucky" only, but a good grower, and as a matter of fact his magnificent Tons have afforded conclusive evidence on that point. Mr. Foster Melliar tells us that though he only beat Mr. Lindsell once, he was lucky enough to secure another win against his Roses, because the man went with them from Hitchen, instead of leaving them alone for awhile, fiddled about with the blooms for two hours in the tent and spoilt them prior to the judging, so that our author, taking a lesson from Mr. Pemberton, kept his blooms in the dark, and won by waiting.

It appears that the East Anglian amateur was not invariably right in his action, for he once "stupidly" congratulated a then unknown gentleman who was staging against him on the beauty of his "moss" (as if the Roses were not worth recognition), and received an icy "Thank you." The gentleman was Mr. Lindsell. Again, we are told of an incident of the chances of a friendly competitor, the Rev. H. H. Horner, being prejudiced in this way. "When, as has happened once or twice, a heavy thunderstorm threatened the day before a show, my little man came dancing up to say, 'It's blowing right away from us, sir, and going right over to Mr. Berners'.'" To this the master of the little man naïvely adds, "I am afraid his unholy glees was rather laughed at than rebuked." The author concludes his paper by calling attention to individual blooms of superlative merit, and expresses the hope that growers of such blooms in future will have them handed down to posterity by the photographer's art. The difficulty, perhaps, would be to catch all of them with the camera at the moment of maximum beauty.

Mr. Shankleton discusses on "Roses for Suburban Gardens," and puts in a plea for standards, as "they seem to lift the Roses up into a freer atmosphere." Very good lists of varieties are given for gardens on the confines of populous centres, the author putting in a word for Hybrid Teas, Rambles, and Japanese Roses of the Rugosa type. Of the last named we can say that they succeed better than any others in parks and gardens in the smoky and murky East End of London.

The editor treats the Rose and the National Rose Society over fifteen pages, in which are recorded the main facts and incidents of the past Rose year. Mr. A. Piper's "Comments on New Roses" appear as fair as they are full—an able, interesting, and useful contribution. Mr. Alfred Prince has a concise chapter on "Climbing Roses," and Mr. Edward Mawley, in his own excellent way, deals with the "Weather of the Past Rose Year," scattering useful hints as he goes along. The issue is good all through, and is published as usual by Messrs. Benrose and Sons, Old Bailey, London.

COSTUS IGNEUS.

THERE are several species of *Costus* known to botanists, but it cannot be said that they are very generally cultivated, notwithstanding the beauty of some of them. We are not, therefore, surprised to learn that "H. Long" has not previously met with *Costus igneus*. As we think it will be interesting to other Journal readers as well as our correspondent, who asks for information, we reproduce (fig. 1) an illustration of this very handsome house plant, which was prepared from one of Sir Trevor

shown in the woodcut. Like most of the *Costus* this species thrives best in a stove temperature, heat and moisture being quite essential to its successful cultivation.

COMPOST FOR PEACH BORDERS.

As "A. D." asks for opinions on the most suitable compost for Peach borders, I have pleasure in giving mine on the subject. The too free addition of manure appears to be the favourite practice with

FIG. 1.—COSTUS IGNEUS.

Lavergne's specimens some years ago. It was exhibited at one of the meetings of the Royal Horticultural Society, and was greatly admired. Flowering during the winter months is its distinctive characteristic, and to insure for it a far greater share of popularity than it at present enjoys. The flowers are that of a rich orange colour, and are usually borne in clusters on the top of the stems. The leaves, too, are decidedly ornamental in appearance, and are produced in crowded masses, as

many when preparing a Peach border. The soil should be good, fresh, and substantial, but not richly manured. The Peach, in the early stages of growth, does not require good food, simply because it comes over luxuriant growth, which is sappy, and not sufficient to ripen its fruit well. So long as the soil is not absolutely sandy, peaty, and lay on the one hand, or so stiff, wet, and cold on the other, and it is may be expected to show itself well. Of course it is as well, in the proper position, to dig at the trees, whether under glass or outdoors, for

without abundance of sun it is not possible for Peaches to succeed in any compost. Farmyard manure added to ordinarily good turfy loam will make the compost too rich in organic matter, but a poor loam containing no turf might have a fifth part added of manure, but no more. The best material for Peaches is undoubtedly good calcareous loam. I have seen them do well in such on a chalk subsoil. Cut the turf from a pasture deeply enough, so that there is not only the turf, but a few inches of the soil below, which is all the better if it contains small stones. Light soil can be improved by the addition of burnt or powdered clay. Old mortar, brick rubbish, or lime, may be added at the rate of one-fourth to any soil, also wood ashes and a sprinkling of bone dust. Give not more than 2 feet in depth of compost, making it firm, and have the subsoil well drained.—E. D. S.

THE recipe given on page 494 last week is far too rich. Peach trees planted in a compost formed of such ingredients would produce very gross shoots, and give the cultivator unnecessary trouble in bringing them into a fruitful condition. When trees are planted the objects desired are the rapid production of fibrous roots and moderately strong shoots, which are the visible evidences of correct root action. When trees of this description are established there is no difficulty in securing a good crop of fruit annually under glass, and no matter how heavy, by the aid of top-dressings, abundance of water, and high feeding generally, the crop may be brought through successfully; but to secure fruits of full size liberal thinning must of course be resorted to. The recipe given below is the one I strongly recommend for adoption in forming composts for Peach borders:—Good fibrous loam 10 loads, lime rubble 1 and wood ashes 1 load, with 1 cwt. of bone meal, and 2 bushels of soot. When turfy loam cannot be obtained a mellow yellow clay answers splendidly if, in addition to the other ingredients above given, half a load of charcoal is added.—H. D.

PEACH trees growing in such a compost as described by "A. D." could not well be a success. The soil would be much too rich to insure prolonged satisfactory results. The necessity of the addition of manure to soil for Peach or Vine border making is best judged on the spot. Presuming that freshly cut turf is employed as the staple of the compost, if this be taken from a position that has grown but little grass, then the addition of a manurial stimulant might with advantage be employed.

Soil too rich in manure is certain to cause trouble in the near future in the form of gumming and the general absence of a full fruit crop. Far better to err on the opposite side, because stimulants can always be provided in liquid form and by surface dressings to assist growth when it is seen by the current shoots that the trees require additional aid. Trees that never make growths larger than the small finger, and more often of the thickness of an ordinary cedar pencil, are not only more easily managed, but give much better results than those that make shoots thick enough for walking sticks.

Turf of ordinary quality requires but little to enrich it sufficiently. The addition of wood ashes, old mortar rubble, and charcoal is quite sufficient. The quantity of each to be increased if the turf is of a heavy retentive character. The great aim should be porosity of the soil. This is improved if broken bricks are freely added at the time of making up the border. Finally I would say, to ten loads of turfy loam, of medium texture, add one load wood ashes and charcoal combined, and two loads of old mortar rubble and broken bricks.

In the process of making the border tread the soil down quite firmly. This is an important detail; but in doing this it is perhaps of even greater importance that the soil be in a semi-dry state, certainly not in a wet condition, as if kneaded together it is not favourable to free root action.—E. MOLYNEUX.

THE question raised by "A. D." (page 494) on the ingredients necessary for making a Peach border, should bring out some interesting reading from several among your many readers who have had such work to carry out. I am not a little surprised that "A. D." should accept and describe the recipe forwarded to him as an elaborate one, and I should certainly think the young gardener acted with much wisdom in soliciting the opinion of such an able critic before committing himself to such an uncertain course of action. I once had to take to a newly formed Peach border, so rich in texture that for three or four years I had to continue an annual course of root-pruning before any useful fruit-bearing wood was possible.

Very strong growth is undesirable in any fruit tree, and it is certainly unwise to foster this by artificial means when, by moderation, it is possible to produce an early crop, and build up a more easily managed tree with less trouble or cost. If good garden soil, which has been proved to suit fruit trees, were substituted to almost or quite one-half of the ten loads, the horse droppings entirely omitted, and the Vine manure also reduced one-half, a compost abundantly rich would be provided for Peach growing. Even then the trees would need rational management, and have some freedom allowed them about their heads.

In the production of vigorous and productive trees, pruning is best done in summer, that is to say, disbudding and pinching should be so manipulated that very little pruning in the winter is necessary. Branches thickly disposed, the points of over-strong shoots stopped before they proceed too far, will, when attention to the usual course of watering and syringing is strictly carried out, result in fruitful growth, even if the trees are vigorous. Clear water only should be given for a long time to newly made Peach borders. If this is given in regular and sufficient quantity, there would be abundant fertility found in the soil to insure the best of results.—W. S., *Wilts.*

[We have other communications on this subject from highly successful cultivators of Peaches.]

FREESIAS AND THEIR CULTURE.

IN dealing with Freesias I do not propose to enter into their history, for whatever that may be, it is certain that these easily grown plants with their deliciously fragrant flowers are amongst the most highly appreciated of those that have come to us from the Cape. It is difficult to say to what we can compare the perfume, but to me it seems to combine the scent of the *Maréchal Niel* Rose with that of the *Primrose*. The blooms, when cut and placed in vases with their own foliage, are very effective, and for early spring use I do not know a more useful plant. This is the more emphasised when we consider that the perfume, unlike that of some flowers, is never overpowering, but always refreshing. In my opinion it is a most charming flower, and abundantly repays any little extra care that can be bestowed on its cultivation. The varieties I grow are *Leichtlini* and *refracta alba*, of which the former is soft yellow and the latter white.

Anyone wishing to grow Freesias can do so from seed, which should be sown in August or September, and if in the former month the young plants may flower the following season. If the seeds are home-saved, they must be sown as soon as ripe. When once a start is made to cultivate Freesias it will be found an easy matter to maintain a good stock, for, unlike some of our other bulbs, it is not necessary to obtain a fresh supply each year if the plants have had proper attention. The most suitable soil is sandy loam and leaf mould, and the seed should be sown thinly to avoid transplanting. The pots or pans may be placed in a sunny position in a cold frame, air being admitted by lifting the back of the frame lights immediately the seedlings push through the soil. It is, however, imperative that draughts be avoided. The plants must be thinned out to eight or nine in a 5-inch pot.

When the plants are firmly established they should have abundance of air to keep them sturdy and strong. It will be necessary to afford a slight shading during the hottest part of the day, and as the pots become full of roots watering must be carefully looked to, while as flowering approaches a little liquid manure will be found beneficial. As signs of rest become apparent the water should be gradually withheld, for herein lies the most important point in Freesia growing—that is, to get the bulbs properly ripened.

In many cases, as soon as the flowers are over or have been cut, the plants are cast into any out-of-the-way corner to look after themselves, and it is obvious that well-ripened bulbs will not be had in that way. When the foliage is quite yellow the pots ought to be placed on a vinery shelf, or in some position facing the south where they can enjoy the full benefit of the sun. There will then be no doubt as to the eventual proper ripeness of the bulbs. When this stage is reached they should be turned out and sorted into three sizes, and then be placed in some cool dry place till the time for potting is again with us.

August is a good time to pot the earliest bulbs, following at intervals of a fortnight or three weeks later and so on, according to the stock or the number of plants required. The largest bulbs can be put six or seven in a pot, and the seconds nine or ten in a 5-inch pot, while the thirds must be disposed thinly in pots or pans, to be grown in a similar manner to the seedlings to produce good bulbs for flowering the following year. The best soil for this potting I find to be composed of two parts each of loam, leaf mould, with one part of well-decayed manure and some coarse sand. If the compost is in proper condition no water will be required until growth commences, and a frame from which frost is excluded or a shelf in a cool house will be the most suitable place for them. Abundance of air in mild weather with a light position will be found most conducive to a dwarf sturdy growth; but when the flowers appear a little more heat may be afforded to a portion of the earliest stock to slightly hasten expansion, the remainder being left to form a succession. Great care should be taken in applying the heat very gently, otherwise the plants will become drawn, and the flowers when cut and placed in water quickly flag.

Freesias are naturally weak plants, and should be supported by neat stakes before they are allowed to fall over. The foliage is very delicate, and will not tolerate much fumigation, even with *XL All*. The effects will not be noticed at the time, but a few days after the leaves may turn yellow at the tips.—(*Abstract of paper read by Mr. G. CARPENTER, West Hall, Byfleet, before the Woking Horticultural Society.*)

CHRYSANTHEMUM MRS. M. SIMPSON.

I AM sending you a spray of what I consider to be the finest of all white flowered Chrysanthemums for use at Christmas. For the last two years I have grown it with Niveus as a test, and I have now no hesitation in according to it the place of honour among white flowering varieties. It is an English raised seedling obtained by Mr. N. Molyneux, Rookesbury Park, Fareham. For producing large exhibition blooms during the month of December it is equally valuable. The florets are lance shaped, of medium width and length, and the colour is pure white. Treated as a freely grown bush, lovely sprays carrying from five to eight good sized blooms on extra stout stems 18 inches long, which render this variety so useful for vase decoration.—E. MOLYNEUX.

[A spray sent by our contributor bears out all he says of Mrs. M. Simpson. It consisted of six or seven flowers of snowy whiteness in one compact truss.]

CHRYSANTHEMUM TRADERS.

SEVERAL catalogues of the great trade growers of Chrysanthemums have come to hand. Judging by what one reads in them I can but paraphrase an old observation, and say, "See how these traders love one another." But, after all, is it real "love" which is in these lists made so apparent, or is it only a little trade "bluff"? We are all familiar with the game of the rival showmen at the fair, who in public denounce each other, but in private are warm friends. The pretended quarrels serve to interest and excite the public, also somewhat to blind them. Is it so in the case of these Chrysanthemum traders? Those gold medals seem to constitute the tone of contention. But when the next distribution comes, and Smith or Brown gets one, why then of the disputants one at least is temporarily satisfied. Still there is the bitter cry of the discontented in print, and no awards of gold medals can wipe it out.

Does it not seem as if, after all, greed for gold in the shape of medals had as much power to influence traders as similar greed has for some gardeners, who are prone to haggle over their little wins at shows. Would it were possible to create amongst all classes of exhibitors a little more love for their products, all so beautiful, and rather less of anxiety to secure the "pieces." But where has not the greed for gold permeated? We may, however, wish to see our Chrysanthemum catalogues free from these bitter complaints henceforth, even if they be based on correct grounds. What do the public care about such trivial things?—A. D.

CHRYSANTHEMUM PROBLEMS.

WHEN we begin to force many varieties of Chrysanthemums out of their natural course to meet our exhibition requirements, which restrict the blooming period to about twenty-one days' duration, and expect every plant to produce blooms as good as if we allowed them to develop in their natural course, we are confronted with results as conflicting as they are tantalising. In a vague way we begin to talk about the wood being under-ripe or over-ripe, as the case may be, without reference to the true character of the plant, and often without any conception of what is really meant by ripened wood as applied to Chrysanthemums. If the extremes of ripeness explain our failures we should at least take care that attention be directed to the intermediate degrees, and especially to that degree which gives the best results.

Ripened wood is not a mere figure of speech, neither is the degree of its ripeness to be weighed or measured except by the study of the character of the plant, the manner of its growth, and a due consideration of the question how the ripening influences are brought about in general, and in the Chrysanthemum in particular. In no other class of cultivated plants do we find so wide a divergence in individual constitutional, requiring separate and individual knowledge, and consequently separate treatment and manipulation to bring them into line with the requirements of the cultivator. We have also to take into account, as affecting the complications alluded to, that the processes of feeding, ripening, securing the bud, and development of the bloom, in the abstract, though looked upon as separate processes, in the concrete are inter-dependent—influencing each other as to largely affect the results in the aggregate. For instance, in addition to sunshine and climatic influences, the ripening processes are largely influenced by the nature and extent of the feeding, as ripeness in some degree is first necessary to induce the formation of the flower bud, and later in a larger degree for the development of the bud into a perfect bloom.

Notwithstanding all this it follows that growth, bud formation, and the necessary degree of ripeness must be so timed that the

climatic conditions are favourable to perfect after development of bloom. Some varieties, of which Mrs. H. Weeks is a type, require a whole growing season to produce one instalment of growth and flower bud which will develop into a satisfactory bloom, whilst other varieties of the Vivand Morel type produce in the same time two or three instalments of growth, each terminated by a flower bud.

This constitutional variation is again illustrated by the numerous varieties blooming in their natural course, each in its season from August to December. When we realise that the process of flowering, as part and parcel of the seed bearing leading up to reproduction, is the result of some degree of maturity (ripeness), and why varieties so nearly related as having one common origin, as, say, the Japanese section, all submitted to the same climatic conditions and the same cultural treatment, should show these widely different degrees of precocity, we are led to inquire the reasons.

It would be easy to generalise, and state that constitutional variation, inherent all through Nature, as shown by the laws of adaptation and the survival of the fittest, would account for such wonderful phenomena; but as this maturing or ripening of the wood is the bedrock upon which the intelligent Chrysanthemum grower must build up the superstructure of his routine culture, it would be well to eliminate from his practice as much guesswork as possible, and try to grasp the full meaning of the term "ripened wood."

From the simple elements plants build up their own structure, and, so to speak, manufacture the basis of life in an increasing ratio concurrently with the demand for further growth. Professor S. H. Vines, the most reliable vegetable physiologist living, puts the matter as follows:—It is the light and heat of the sun which supplies the energy, and the green chlorophyll of the leaf is the means by which it does it. Interspersed amidst the protoplasm, which is the living principle, or the substance endowed with life, and carried along with most of its movements within the cell walls, are numerous little spongy bodies penetrated through and through with the chlorophyll or green colouring matter. These minute bodies are known as the chloroplastids, and are the nucleus of the starch granules, which result from a series of chemical changes, and form the basis of the ternary or carbo-hydrate series of compounds, which will be further referred to. The protoplasm is of a more complex character; both it and the chloroplastids are built up at great cost and energy to the plant, and consequently we find it takes good care that it is used to the best advantage; they have a great deal of work to do with very little material. The chloroplastids are ranged along the inner walls of the cell, like rows of buns in a shop window, and appear somewhat of the same shape. When the sun shines brightly they come to the surface and expose their edges to it; if the sunshine is feeble they lay their flat sides up so as to absorb every available ray that falls on the leaf; but should the sunlight be very intense they are shrunk away into that part of the cell furthest away from the light. The object of these movements of the chloroplastids is to get a maximum of work with the least possible waste of energy. As the cell sap with its mineral salts in solution is brought up from the roots to the leaves, it comes in contact with the products of assimilation in course of manufacture in the chlorophyll cells; the salts take their part in the elaboration of the nutritive materials of growth, while the water is transpired through the cell walls into the intercellular spaces, thence into the open air.

This wonderful adaptation of the chloroplastids to the intensity and degree of sunshine in connection with their special functional work is as beautiful as it is wonderful, and, in the light thus thrown upon it, we need not be at all surprised why varieties of the Chrysanthemum having the same parentage should vary in the time needed to acquire the necessary degree of maturity (ripeness) to induce the formation of the flower bud as leading to reproduction. In simple terms it may be put that some varieties are endowed with power to that end of doing more work (viz., the early varieties than the later varieties) during the time the sun shines, in a lesser or greater degree according to the amount of sunshine available, the assimilation of starch as the basis of the ternary compounds, carbon, hydrogen, and oxygen goes on when the sun shines, more slowly if the weather is dull, in the dark ceasing entirely.

As showing the necessity of sunshine, and the enormous energy evolved by the chloroplastids in setting free the carbon of the atmosphere to be chemically recombined in building up the structure of a plant, we have only to note the large proportion of carbon of which it is composed, with the fact that the atmosphere as the only source of it available to the plant contains only four parts in 10,000, and without carbon in its due proportion there can be no starch, and as cellulose of which the cell walls are built is alike to starch in the proportions of its chemical elements there could be no structural carbon skeleton of the plant. The assimilation of starch is the first of a series of chemical changes of the ternary compounds, and later of the more complex nitrogenous compounds, which are passed on to the growing point and utilised in building up the cell walls, and furnishing the living cell contents.

During continuous daily sunshine these complex compounds are formed in greater abundance than can be utilized for the growth, the surplus is stored by as a reserve to be drawn upon in the formation of flowers and seed. Wood fully developed and its vessels stored with these products of elaboration is the measure of its ripeness, as understood in its true sense, and this is what our professional instinct swears by.—T. G. W.

(To be continued.)

TOMATOES AGAIN.

WITH the beginning of the new year growers of Tomatoes on a large scale will commence work in earnest. Many seeds have doubtless been already sown—in fact, our first sowing was made a fortnight ago; but the plants from seeds sown at the present time come on so quickly with the lengthening days that there is little, if anything, gained by sowing before the 1st of January. Inserting a single seed in a small pot is sometimes practised in private gardens; but when thousands of plants are grown this is rather too tedious a business. I sow in shallow boxes, placing the seed about half an inch apart, the receptacles being placed in a propagating house where a temperature of 70° is maintained. In three days the seedlings are visible, and as soon as they are large enough to handle they are transplanted to other boxes, being set about 1½ inch apart, watered, and placed on a shelf or temporary stage near the glass.

If kept in a temperature ranging between 60° and 70°, according to the weather, they grow sturdy and short-jointed, and yet make rapid progress. The important point to act upon at this stage is to pot the plants before they become in the least crowded. Failure to act soon enough in this respect has often brought the box system into disrepute, but I have proved to my own satisfaction that, when properly managed, as good plants may be produced by it as by any other. The plants for the early house I like to place in 6-inch pots, and get them well rooted in the soil before planting out, as this gives the opportunity of keeping them very close to the glass for a longer time than when they are planted from 4-inch pots. All cultivators like to see their first truss of flowers close to the ground, and by giving this extra shift the object in view is promoted. For this second potting a suitable compost is formed of three parts old turfy loam and one part hotbed manure, the soil of course being pressed very firmly.

Various methods of planting have to be adopted according to the style of house in which the plants are to be grown. Let us take the case of one built for Tomatoes, in which the plants are placed in the natural soil. If Tomatoes are to be planted for the first time in it no other preparation than that of digging and levelling will be necessary, as it is undesirable to make the soil too rich; fertilisers can easily be applied when the fruit is swelling. Now let us suppose we have a border which has already been cropped once or twice; in this case I should not care to fork in farmyard manure, but rather rely on a dressing of lime and kainit, the latter at the rate of 3 ozs. to the square yard, then when a good quantity of fruit was swelling manure could be employed as a top-dressing.

Plant houses are now in nearly all establishments used for Tomato growing during the summer, and in such it is generally necessary to plant on the stages. This plan I adopted last season with great success. I fastened boards 9 inches in depth, and about 14 inches from the wall sides of the house, a little rough turf was placed in the bottom of the enclosure, which was then filled with ordinary garden soil, rather inclined to be sandy, yet fairly bolding in character. In this the plants were a decided success; and as such soil has to be cleared out each year and replaced with fresh, trouble from eelworms is reduced to a minimum.

The object of most cultivators is to get as many bright, clear-skinned fruits of moderate size as possible from a given space. Some set their plants only a foot apart, but I think that nothing is gained by such close planting. From 14 to 17 inches I find suitable, but such strong growers as Challenger require the greater distance. Should the soil be in the least wet when taken into the house it ought to be thrown up in the form of a ridge till fairly dry, and then pressed very firmly as planting proceeds.

Varieties.—For early use Sutton's A1 is a grand cropper, and although the fruit is corrugated it is an open question if early in the season it does not prove more profitable than the smooth varieties. Among the latter Frogmore Prolific and Sutton's Eclipse are two of sterling merit. The latter I tried for the first time last year, and shall this season grow it extensively, as it produces enormous clusters of brightly coloured fruits of the right size. I believe Challenger will carry as great a weight of crop as any Tomato grown, but the fruits are a trifle too large. I think, however, by selecting medium-sized fruits for seed I shall in time alter its character. At any rate I shall not discard it yet, as it grows so well, and on that account is useful for planting among the centre of span-roofed houses. Up-to-Date I hope to give a trial this season. If it comes up to its reputation it must be a wonder indeed.—H. D.

EELWORMS IN VINE ROOTS.

A FEW weeks ago a correspondent, "E. R., junior," sent a sample of Vine roots differing from any we had hitherto seen, and after satisfying ourselves that the enemy was not the dreaded phylloxera, Mr. Abbey was requested to bring to bear on the dissected nodosities his 500 power magnifiers, and see what he could find. He has done so, and was thereby made a happy man during Christmastide. He found colonies of eelworms that gladdened his heart, inasmuch as they were the first of the kind he has discovered feasting on the roots of the Vine, and he believes a similar case has not been recorded. If that is not enough to make an eelworm man bappy we do not know what is, and we may be sure the discoverer would not have missed this lucky find for a dozen of the fattest turkeys in the land. Here follows the record, with illustrations.

"E. R., junior's," very fibrous, yet tuberculated, specimens of Vine roots had a singular appearance. A small portion is shown with exactitude in the illustration (fig. 3), natural size.

The excrescences were confined to the fibrelets of the apparently current year's formation, or one-year-old roots (a). A few fibres showed no trace of the attack (b); but most of them were "knotted," and for the chief part at the extremities (c). A few nodosities were found on the branchlets (d), but none on the part of the main root, as I take it, more than one year old (e to f.)

The pest, therefore, was incapable of piercing through the cuticular cells of two-year-old roots, or of penetrating them to the cambium or formative layer, which is necessary for the growth of new (cellular) tissue and the development of an excrescence, or warty swelling. This case is very important, as indicating the power of the enemy in its attacks on the roots of the Vine. The creature, whatsoever it may be, thought I, while generally preferring the tender fibrelets, has also attacked the somewhat older portions of the current year's roots at d; but these, on careful examination, were found to consist solely of dead tissue, and the attack had taken place whilst the tissues were younger and

FIG. 3.—NODOSITIES ON VINE ROOTS.

References.—a, excrescences on young fibrelets; b, clean fibres; c, chief attack or swellings at extremities of fibres; d, nodosities on branchlets or older parts of roots; e to f, portion of root free from excrescences (all natural size).

softer. There is no "guesswork" in this case. Tangible facts were plain enough, and these only I describe and show.

There was nothing in the dead nodosities, but in some of the partly dead and partly living were found certain bodies, fig. 4, A, an egg, with a nucleus (g) and various similar bodies with different internal structures—the nucleus developed into several, and at last

FIG. 4.—ROOT-KNOT EELWORM, *HETERODERA RADICICOLA*.

References.—A, egg; g, nucleus; B, eelworm developed in egg or sac; h, eelworm ready to come into this great world of things; C, female larva; D, male larva; E, full-grown female larva; F, full-grown male larva; G, larva encysting; H, more advanced stage of encystation of female; I, eelworm in cyst; J, head or neck of cyst; K, vulva of eelworm; L, perfect male; M, gravid female; N, eelworm proper; O, eggs; P, mouth of or neck of cyst (all enlarged 260 diameters).

into eelworms, one such body being shown at B, with the eelworm coiled up inside (h). There were hundreds of both forms, not any larger, but many much smaller than those figured. The number of such emerged from the eggs were legion; one stout (C) I took for a female, and one thinner and longer (D) I considered was a male. Both larvæ or young animals evidently grow, for there were some larger, still stout, E, and others thin and agile, F, respectively female and male.

The sizes are maximum of larvæ or young eelworm, but there were also hosts of the form shown at G, the eelworm encysting—that is, enclosing itself in a vesicle. It, however, never loses its head, but the tail of the creature disappears by degrees, as shown at H, while the animal inside brings its head and tail together, and passes round the cyst (i), and the head in the case of the female remains intact (j). The one shown is a female, and has a vulva (k). I did not find a male cyst. The "lord" of the family, however, made stir enough in the microscopic ocean—a veritable sea serpent, and is shown at I. It is root-knot eelworm, male, *Heterodera radiculicola*. And lastly there were several gravid females. One, as shown at J, is covered all over the body with a lace like covering—that is, the flask, for the eelworm (l) lives inside and produces a vast number of eggs (m). She draws in nourishment through the mouth of the flask (n), and the flask-like body is simply a sac of eggs of the size as shown at A. Then all is over, the sac bursts because the mother is dead, and the eggs soon hatch out the young eelworms.

That was everything there is belonging to root-knot eelworm, every stage from egg to egg again, and all from one partly decayed nodule of the Vine root. I believe this is the first recorded instance of root-knot eelworm having been found on the roots of Vines, and is notable for only attacking the young tender fibrelets. We know that Cucumbers and Melons readily succumb to the pest, and Tomatoes also, but less speedily, as the roots are somewhat more resistant. The eelworm finds a fresh field in Vine roots—perhaps made tender by high cultivation.

With the life history from year to year, it will suffice to say that

the eelworm lives in the larval stage for a considerable period coiled up much after the manner of a snake, thus surviving the winter in the absence of living food-plants. I do not know what heat Vines will bear at the roots, but I have killed wireworm and grubs of the Vine weevil with a soaking of water at 115°, yet eelworm does not die under a temperature of 125°. I do not think that water at 135° would hurt Vine roots, but I should hesitate before giving a Vine border a soaking at that temperature. Such hot water may answer well enough experimentally, but treating a Vine border is quite a different affair, as the soil varies greatly in staple and retentive power.

For the reason given it has been advised to use one wineglassful (2 fluid ozs.) of Little's soluble phenyle to 3 gallons of soft water, and apply that quantity by means of a rose watering can per square yard. This solution, one part in 480 parts water, will not hurt Vine roots, and it will kill those eelworms that it reaches. This I have proved over and over again, but I should not use it on a border close and yet. Lime would be better where much animal manure or stable drainings have been used. Apply 1 lb. of best chalk lime, freshly burned, per square yard; slake with the smallest amount of water necessary to cause it to fall to fine, apparently dry flour, and spread evenly on the surface. Leave it for a night, then apply $\frac{1}{2}$ lb. of kainit per square yard, and fork in as deeply as may be done without injuring the roots. Leave for the winter, rough, and when about starting the Vines apply a dressing of dissolved bones, dry and crumbling, 4 ozs. per square yard, pointing in very lightly; and later use nitrate of soda, if a light soil; if heavy, sulphate of ammonia, $\frac{1}{4}$ oz. to 1 gallon of water, for watering with. If soluble phenyle be used at the starting of the Vines there will not be any need to apply either the nitrate of soda or sulphate of ammonia.—G. ABBEY.

GROUPING PLANTS FOR EFFECT.

WHAT TO IMITATE AND WHAT TO AVOID.

THE grouping of plants for effect at our horticultural exhibitions has, for some years now, been one of the chief attractions, and I am of the opinion that more people will be found closely scanning the groups than almost any other section of the exhibition. Much has been done by our leading societies to encourage the art, yet, in my opinion, there is ample scope for still further developments. It is many years since I first saw a group of plants arranged for effect; it was at the great Whitsuntide exhibition at Manchester. I have forgotten who staged that group, but by no means what it was like. It was composed of splendidly grown plants (I know this, because I saw them before they were put together), and so arranged that not a twig was allowed to show itself above its neighbour, a gradual slope being formed of which any thatcher might well be proud. At that period this was thought very fine, and doubtless if such men as Messrs. Wills, German, Ward, Cypher, and others had not had different ideas, we should be still going on in the same way.

The late Mr. Wills has always been accredited with doing more to improve the artistic arrangement of plants I believe than almost anyone else (and with good reason); but it must be borne in mind that the greater part of his successes were non-competitive, and being so, he had practically a free hand as regards space and selection of material. This is not so with those who compete as they are bound by the schedules. The man who, in my opinion, first struck the right note in arranging groups for competition, and led the way to the present state of things, who to-day, although we hardly hear of him, could, I honestly believe, give points to any exhibitor in this particular branch, is Mr. Samuel Thacker, of Nottingham, an amateur. This is not very flattering to professionals, but I believe it to be perfectly true. Some may assert we get nothing new now, the thing is worked out, and it must be admitted there is something in this. Yet I think there is no limit to the possibilities in this direction. The goal only wants making a little more difficult; in other words, the exhibitor has done what can reasonably be expected of him; now the schedule makers must step in and lengthen his rope. I have more to say on this later on.

"A group of miscellaneous plants arranged for effect on a given space" is usually the wording of schedules. What is effect? It may mean anything, according to the capabilities of the person asked to adjudicate. I will try to describe my idea of an effective group of plants. Before a man can say he considers anything perfect he must have an ideal in mind as to what is "perfection." I place Nature as my ideal of all that is beautiful, and everyone will admit that no work of man can compare with Nature. Well, my idea of a perfect group of plants—though, as a matter of fact, I have never seen one that quite satisfied me—is that each individual should be made to look as though it had grown in its position. I have never visited any tropical countries, but I have seen pictures, and heard them described in a way which has fairly made my mouth water, and has made me yearn to lift a solid block—say about 400 square feet—bring it home, and exhibit it at one of our leading shows, then we should have a group for effect. I have seen, in our own country, little bits which would take much beating.

Having taken Nature as our ideal we ought to try and show her at her very best when we make a group, for under natural conditions there is a tendency for vegetation to grow too thickly to permit of all the beauties it contains being seen when, as at shows, we are only allowed to stand in front and admire. It is different in its own home, where we can

wander in and out looking for the tit-bits, so all will agree that every plant ought to be so placed that it can be clearly seen from the point of observation. Then, again, we have the advantage of being able to unite forces, such as a detachment from India, one from Australia, a third from the South Sea Islands, and so on—gems from anywhere and everywhere to unite in one grand international congress; and this is without doubt a great advantage to an exhibitor. It may now be advisable to point out a few things it is better to avoid.

In the first place, never try to make a group similar to what has been seen elsewhere. Nature does not recommend this, and herein lies its greatest charm. No one ever saw two pieces of natural scenery exactly alike, so strive for originality. Never attempt to make a pattern, as is done in carpets. I believe this is one of man's worst attempts to be artistic. In plant arrangements you often see Nature admirably represented in the body of the group, and the man, true to his mechanical instinct, steps in to improve by placing round its neck a frill of perhaps blue Lobelia, or anything according to fancy. Never take too many plants to a show, as one of the worst and commonest of mistakes is overcrowding. Avoid a late start. Of course there are men who pride themselves on being able to arrange a group quickly, and no doubt some do take longer than others. But a good start often saves worry at the finish, as this state frequently leads to disaster. If there is time to spare it can generally be used in "touching up," which otherwise would have to be left undone.

It is necessary to use many artificial aids in making groups, but not one must ever be visible. Nothing mars the effect more than to see bare pots, ugly stakes, matting, drain pipes, tables, flower stands, and other things. Another common error is going to see what fellow exhibitors are doing, for it distracts the mind, and prevents preconceived ideas bearing fruit. Never let a plant touch its neighbour, or peculiar effects are liable to result. For example, I have seen a beautiful Croton made to look as if *Lilium auratum* blooms were growing on it, splendid heads of *Hydrangea paniculata* peeping from a clump of Maidenhair, and the tops of graceful Palms rising from a mass of red, white, and blue. Is this right? Certainly not.—(Read by MR. G. WILSON, Swanland Manor, at a meeting of the Hesse Gardeners' Association.)

[Though we regard Mr. Wilson as a master in the art of grouping plants, we join in the tribute which he deservedly pays to Mr. Samuel Thacker, who has produced the best effects with limited means that we have seen at any show.]

(To be continued.)

THE YOUNG GARDENERS' DOMAIN.

NERINES.

IN answer to "Parvo," regarding Nerine culture, especially in relation to the temperature stated on page 367 last vol., I may say that the temperature of 45° as a night minimum, and 80° to 85° as a day maximum with sun heat, and 50°, or a little above the night minimum by the use of fire heat on dull days, has the following advantage—with a due proportion of light, moisture, and food material it would tend to stimulate their growth, increase the assimilation in the leaves, and ultimately produce bulbs which would be richer in matter for the origin and development of floral organs.

I think we should heartily encourage this work of the leaves, and one way of doing so is to maintain a genial temperature by "bottling up" the sun heat, although in doing so the temperature may rise to 85°. In giving this number I have in view a shallow structure with the plants near the glass. In a large house the circumstances might be altered to suit the case, especially if other plants were to be considered. A Peach house shelf would be a good place for Nerines after flowering, and by careful watering and feeding a fair degree of success would be attained, but I question whether the flowers would be so large, their colour so brilliant, or their texture so strong and lasting as would be attained by giving the plants more liberal treatment, growing them in a structure specially suited to afford them a higher temperature. Regarding the influence of temperature on the longevity of a bulb I can give no distinct opinion.

The species which "Parvo" mentioned are about the best. According to the Kew "Hand-list" *Nerine crispa* is synonymous with *N. undulata*, and *N. corusea* with *N. sarniensis*, the latter in each case being the correct name. Three of the named garden hybrids are worth special notice—*N. elegans* (*flexuosa* × *rosea*), *N. Meadowbanki* (*sarniensis* × *Fothergilli*), and *N. Manselli* (*flexuosa* × *Fothergilli*). The last is a late bloomer, flowering towards the end of November, and continues to flower in early December. It is slightly lighter in colour than *sarniensis*.—X. L. C. R.

STATICES.

IT seems to be a hard and fast rule with some growers to rest all plants alike through the winter, and I am of the opinion that this is the cause of many failures, especially with Staticeae, which do not appreciate being rested during the winter months. I do not wish to infer that they must be kept growing at the same rate in the winter as during the summer, but simply that they should just be kept steadily moving. My observations teach me, too, that Staticeae like a closer atmosphere than do many greenhouse plants, but they must have a little air, and be kept close to the glass, though not too much exposed to the bright sun, or they will quickly fall a prey to red spider, and the leaves will assume a sickly, rusty appearance.

Staticeae may be easily propagated from cuttings made of the shoots in early spring, which should be inserted singly in 3-inch pots filled with a mixture of good loam and sand in equal parts. They must be kept under a bell-glass or in a propagating frame in a temperate house, when roots will soon be emitted. About the latter end of June or the beginning of July the young plants may be transferred to 5 or 6-inch pots, using a compost of three parts of fibrous loam and one part of coarse sand. Stand them in a temperate house, and syringe every afternoon unless the weather be very dull and damp. During the winter months they may be kept in a rather lower temperature say, 45° to 50°, on a shelf near the glass if possible, as they will then form stiffer and sturdier growths than would otherwise be the case. As abundance of water is essential during the growing period the drainage must be efficient, or stagnation at the roots will bring partial or total collapse. When in flower they must not be syringed, or the blooms will damp. When the shoots have grown sufficiently long they should be trained down towards the rim of the pot, so as to form shapely plants. It will be found advisable not to allow the young shoots to flower too much the first season, as it interferes materially with their growth.

Thrips and red spider will be found troublesome, and do serious mischief unless attended to with promptitude. Great care must be exercised in using insecticides, or they will cause injury to the leaves, and thus partially spoil the beauty of the plants.—ONE OF THE SCHOOL.

HARDY FRUIT GARDEN.

Cleansing Fruit Trees of Moss and Lichen.—When fruit trees and bushes are infested with moss and lichens they present an unsightly appearance, and means ought to be adopted which will eventually clear the stems, branches, and shoots of these incrustations. Apparently no harm results from their presence, but if allowed to remain it is certain that insects will form a lodgment, to the detriment of the health and vigour of the trees. If more than ordinarily thick incrustations are present, scrape off the thickest portions with a piece of hoop iron or other suitable tool, but avoid cutting or wounding the bark.

The operation is best carried out when the trees are moist. This effected, well brush or wash the trunk and branches over with hot lime-wash, which decomposes the vegetative growth and destroys any insect life present. The slenderer shoots of trees and bushes may, if necessary, be cleansed by distributing over them finely powdered lime in damp or foggy weather. The lime dressing is excellent for Gooseberries and Currants, as it will not only cleanse them from green growths, but of scale or red spider, while that which falls to the ground acts beneficially, destroying the larvæ of caterpillars and neutralising the acidity of over-rich soils. Brine applied on the trunks and larger branches with a scrubbing brush is also excellent.

If the glaring whiteness of lime is objected to, this may be toned down by the addition of soot. Some prefer the further addition of sulphur, about an equal quantity being used with the lime and half soot, the whole mixed in a soapy solution, and applied to the convenient parts.

Destroying American Blight.—Apple trees affected with American blight are also usually attacked with canker, the wounds in the bark and the excrecences formed by it providing safe refuge for the insects. The cankered parts may with advantage be pared smoothly, then painted over with a mixture of Stockholm tar and soft soap, or the latter and petroleum, a pint to the gallon of strong soap solution. Brush well into the affected parts. Gishurst compound and other in ecticides may be employed if preferred, but in bad cases a petrolum emulsion, formed either with soft soap or castile soap, is the best.

A General Cleanser.—Trees or bushes that do not require special efforts to rid them of pests should be sprayed with Coates' soda and potash solution. This is made by dissolving 1 lb. of caustic soda and 1 lb. of crude commercial potash in 10 gallons of water. This preparation ought only to be used when the trees are dormant. It is excellent for thoroughly cleansing the bark of all infestations, whether insect pests or mossy or lichenous growths.

Outdoor Vines.—*Pruning.*—Mild weather should be chosen for carrying out the necessary pruning required by Vines on outdoor walls or trellises. Aged branches with elongated and knotty spurs might with great advantage be cut out and their places taken by vigorous young canes that are well ripened. It requires some forethought to have suitable young canes to take the place of old rods. Those which may be required should be selected during the growing season, and shortened to about 4 feet at the winter pruning. As a rule new canes intended to renovate the Vines ought to be originated as near the base as possible, but to fill vacancies or to substitute new growth for old in any part, well ripened lateral growths may be laid in, pruning down to good firm buds.

The majority of the lateral shoots on the spurs must be shortened to one or two buds, but seize the opportunity where two or three laterals issue from one main spur to remove those furthest away from the main stem. In this way spurs are prevented from extending too far, there is

less danger of crowding, and the appearance of the Vines is greatly improved. However desirable it may be to furnish the Vines with vigorous young wood, instead of useless old, the former must not be crowded, but so disposed that sufficient room for the lateral growths bearing fruit in summer can be found.

Cleansing.—After the pruning, the branches, spurs, and canes ought to be well washed with a softsoap solution, 4 ozs. to the gallon of water, or some insecticide of similar strength, as Vines growing on hot, dry, outdoor walls, are subject to red spider in summer.

Peaches and Nectarines.—The principal pruning of these may be deferred for the present, but as a means of checking the growth of trees planted on a warm aspect it is desirable that the young wood should be unloosed from the walls so that it may have the benefit of the retarding influences of the cold weather. The main branches are better left secure, otherwise they may be damaged by the wind, which will not injure the young and willowy shoots, but harden and ripen their tissues.

Heading Down Trees for Grafting.—Healthy, but fruitless Apple trees, intended to be grafted with superior varieties, may have the strong branches headed down to near the point selected for the insertion of grafts.

Scions for Grafting.—These ought to be carefully selected, tied together in separate varieties, labelled, and laid in in moist soil under a north wall. In that position they will be kept in a dormant condition until the period for grafting arrives.

FRUIT FORCING.

Cherry House.—Where the house has been closed since the middle of December, and frost excluded, fire heat may be applied to secure a temperature at night of 40° when cold, 45° when mild, and 50° by day, allowing an advance of 5° to 10°, or even 15° from sun heat, but not without a free circulation of air at 50°, and admitting it abundantly in mild sunny weather. Syringe the trees occasionally, but do not keep them dripping with water, and take care that they become fairly dry before night. If the roof-lights have been off the borders will not require water for some time to come, yet the soil must be kept in a moist condition. Trees in pots must be regularly attended to, not allowing the soil to become dry, but afford a supply when needed. If any of the trees are unsuitable now is a good time to introduce new ones in their place. Trees that have been grown against and trained to a south wall for three or four years, and lifted occasionally, are the best. Early Rivers, Black Tartarian, Governor Wood, and Elton are suitable varieties. Empress Eugénie, a variety of the May Duke race, is very fine for forcing in pots.

Cucumbers.—Seed must be sown to raise plants for the early spring supply of fruit. We still hold to a carefully selected stock of Telegraph as an all-round variety. There are many excellent varieties, and every grower has his particular favourite. The seeds may be sown singly in 3 inch pots, in a rich mould, which has been scalded some time previously with boiling water, especially in places liable to attacks of eelworm, leaving room for top-dressing the plants when they require it. Plunge the pots in a brisk bottom heat (90°) near the glass, and cover with a pane of glass, which must be removed as soon as the plants appear. Where there is not the convenience of a hotbed, the pots may be stood on a shelf near the roof, covered with a pane of glass, and in a genial atmosphere, with a night temperature of 65° to 70°, rising to 80°, 90°, or more with sun, the plants will come up sturdily. A little air may be given at 75° in very closely glazed houses, but be careful to avoid a check of any kind, especially sudden cooling or drying of the air.

Figs.—*Early Forced Trees in Pots.*—Those started in November or early December will need the temperature gradually raised to 60° at night, but 5° less in severe weather, and 65° from fire heat by day when the growths are developing, with 70° to 75° or more from sun heat. Avoid, however, a high temperature by artificial means, as the sturdier and shorter jointed the young shoots and the stouter the leaves can be kept the greater will be the chances of a satisfactory first and second crop. The first crop is best secured by keeping the growth somewhat closely pinched. Syringe the trees twice a day, except in dull weather, when damping in the morning and early afternoon will be sufficient, as less moisture will be needed where the fermenting materials aid in furnishing the heat, than where reliance is solely placed on fire heat, and avoid a saturated atmosphere in dull weather. As the fermenting materials settle firm them well about the pots, and add more, taking care that the heat does not exceed 70° to 75° about the pots. Place some turves, about 2 inches thick, grass side downwards around the rims and on the surface of the pots, extending inwards about 2 inches, so as to form a dish, and outwards over the rim towards the fermenting materials, with a view to encourage the surface roots to extend. Water the trees and turves with weak liquid manure, and the whole surface will soon become a mass of roots, and they may then, the hollow or dish being filled with rich material, be fed to any extent with liquid stimulants, or a sprinkling occasionally of bone superphosphate five parts, nitrate of potash three parts, and gypsum one part, mixed and kept perfectly dry, can be applied.

Fig Trees Planted in Borders.—The first house of these should now be started, and the fruit will be ripe towards the end of May or early in June, when the varieties consist of Brown Turkey, Pingo de Mel, and White Marseilles. The first is far away the best Fig for general purposes. The borders should be brought into a thoroughly moist condition by repeated waterings, but not going to the extreme of making them sodden. Syringe the trees in the morning and early afternoon when fine, or er-

wise only damp the floor and borders so as to maintain a genial atmosphere, for one that is close and damp has a tendency to induce soft growths and is unfavourable to the first crop of fruit. Maintain a night temperature of 50°, 55° by day artificially, and allow an advance of 65° from sun heat, with a free circulation of air.

Melons.—Plants raised from seed sown now will ripen fruit by the end of April or beginning of May in light and well-heated structures, not otherwise, and contingent on the weather being favourable to their growth. The seed should be sown singly in 3-inch pots, half filled with fibrous loam and leaf soil, plunging the pots in a hotbed of fermenting materials, and covering them with a pane of glass, which must be removed as soon as the plants appear through the soil. Where there is no bottom heat the pots may be placed on shelves about 1 foot from the glass in a house with a temperature of 60° to 65° at night, and 70° to 75° by day artificially, with a piece of glass over each, and in this case the plants will be hardier and sturdier, and less liable to suffer from damp, than those in a hotbed. When the seedlings have made an inch or two of stem they should be top-dressed with warmed soil and kept well up to the glass or in plenty of light, so as to secure a sturdy growth. Varieties are plentiful, and growers have their special favourites, so that selection would be superfluous.

THE BEE-KEEPER.

MOVING BEES.

WITH the advent of the New Year and the sun at its lowest ebb the bees are clustered in their hives. It will be advisable for bee-keepers to make an examination of the position in which the hives are placed, so that they may be removed to a more suitable spot if necessary. Beginners often make a mistake in carrying out this operation, but it is a well-known fact to bee-keepers of experience that bees may be moved with impunity at any season if certain rules are carried out. For instance, a strong colony of bees may be removed from its original stand during the height of the honey flow; but it must be done at night, after the workers have returned to their hive. The entrance must be closed, and the bees should not be liberated within two miles of where they previously stood, or many of them would return, and thus be lost.

The above shows how important it is that any alterations that may be necessary in the apiary, whether large or small, should be done during the short days of winter, when few bees are on the wing, as at this season all that is necessary to insure success is care and steadiness in handling the hives, and not a bee will escape. If the weather is very mild it will be advisable to close the entrance to the hive for a short time; the operator need then have no fear of being molested by the bees, in case of an accidental shaking of the hive.

POSITION OF STOCKS.

Before moving the bees it will be advisable to study the position in which they are to stand. If possible choose a sheltered spot, where they are protected from high winds. Bees thus favourably situated invariably come out strong in the spring, owing to the bees commencing to breed early, and thus early swarms are obtained. The favourite position faces south-east, with the protection of a wall or fence at the back of the hives, as the sun then shines on them from early morning till late in the afternoon. If there is also a slight shade from the trees growing a few yards away so much the better. Local conditions, however, govern the result to a considerable degree.

If extracted honey is the chief aim of the bee-keeper we would advise him to study his own convenience even more than the position of the stocks, as, taking one season with another, it will be found that as much honey will be obtained from a colony facing due west as from a stock in any other position, so long as the all-important shelter is provided.

OTHER ASPECTS FOR HIVES.

The majority of the hives in our apiary face due west. They are not placed in this position because we consider it is the best—as a matter of fact many bee-keepers would consider it the worst, because we have very high winds from that quarter. Other stocks are facing various directions, but all have the shelter of a fence of some description. The result is much the same from one as the other. The reason the majority of our stocks are in what many would term an unfavourable position is for the convenience of extracting. It is a great advantage—in fact, it is a necessity—when honey is becoming scarce, to be able to extract it from the combs in a building where the bees cannot gain admittance. In our case it is the convenience of a building that has caused us to have our bees near at hand for manipulating, in preference to taking them some distance away to what may appear a more suitable spot, but from experience it would be only so in theory.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Cleome heptaphylla (*M. G. R.*).—This plant is of moderate height, with seven-lobed leaves and white flowers, the long purplish stamens of which contrast with the spreading white petals. The flowers are produced freely, and when well grown the plant possesses a light graceful appearance. It can be treated similarly to many other annuals from warm climates—namely, the seeds are sown in heat, and the young plants grown in light soil in the stove or placed during the summer in the conservatory. It flowers late in summer and autumn, and lasts some weeks in good condition with ordinary care.

Potting Liliun auratum (*H. P. J.*).—Though fresh sound bulbs often answer if potted at once, or planted as soon as the ground is in suitable condition, those which are more or less shrivelled as often fail to produce satisfactory plants. It is an excellent plan to place fresh cocoa-nut fibre in boxes or flat baskets, and in this press the bulbs a third to half their depth, and there let them remain in the potting shed for a few weeks, or until incipient roots are visible at the base of the bulbs, then if they are potted, or planted in a suitable medium, good growth may be expected. After potting it is a good plan to plunge the pots over their rims in cocoa-nut fibre refuse, or other light damp material, in a frame, or even outdoors if the pots are stood on a base impervious to worms, and drenching rains are thrown off the plunging bed by a shutter or other means.

Winter Dressing Fruit Trees (*Kewhurst*).—The caustic soda and potash solution advised in Cousins' "Chemistry of the Garden" is best applied by means of a spraying apparatus. It may, however, be applied by means of a half-worn, clean, painter's sash-tool, but not in an excessive amount, it sufficing to just wet all the parts of the tree and reach into every crevice, so as to get at the hibernating foes, such as American blight and codlin moth; it will kill most pests and their eggs, and also free the trees from lichen and moss. The American blight should also be seen to in summer, and the infested parts touched with methylated spirit by means of a small brush, and the codlin moth prevented by spraying with Paris green shortly after the Apples and Pears are set. This will also make an end of leaf-eating and fruit-devouring caterpillars.

Forced Figs in Pots (*Manouian*).—As the terminal buds have started, you must take advantage of any mild weather that may prevail to increase the mean temperature of the house, as when Figs are fairly started into growth they delight in heat, moisture, and light. The glass must be kept clean, and air admitted so as to prevent the glass being continually covered with moisture, but seek increase of temperature from fire heat combined with sun heat in preference to maintaining a high temperature in dull weather, and especially at night, that will cause any great advance in growth at those times. Maintain a night temperature of 55° to 60°, ventilate a little at 70°, losing no opportunity of admitting a little air when the morning promises an increase from gleams of sun, and close sufficiently early for the temperature to run up to 80°. Syringe the trees and walls twice a day on fine days, but when the weather is dark and wet omit the afternoon syringing and damp the floors in the evening instead, as the trees are weakened and the foliage made soft by keeping them wet during the night, therefore always allow the trees to become fairly dry before nightfall. Be careful not to allow the heat about the pots to exceed 70° to 75°, and if the materials are heating too violently turn them as a means of reducing the bottom heat, but it ought to be kept steady.

Costus igneus (*T. Long*).—The illustration and note on page 11 will we hope give you all the knowledge you require about this plant, which it is trusted you may in the near future see in flower, when no one could fail to admire it.

Tuberous-rooted Begonias from Seeds (*Nemo*).—Prepare pans by well draining and then filling with a mixture of loam and leaf soil sifted fine, adding a sprinkling of silver sand. Make the surface perfectly level, and give a gentle watering, or enough to well moisten the soil. It is a mistake to surface over with sand. The seed should be sown about three hours after watering the pan, quite on the surface, thinly, and regularly. Avoid letting it get together in patches. It will germinate most surely if given the benefit of a brisk, moist, bottom heat. Cover the pans closely with squares of glass, and shade till it is seen the seeds have germinated, after which light should be gradually admitted, but no sunshine ought to reach the seedlings. The soil must be kept uniformly moist, but no water should be applied to the surface. Whenever necessary partially immerse the pans in a pail, tub, or tank of lukewarm water, the soil thus becoming moistened upwards. Tilt the glasses slightly, when the seedlings are plainly visible, by way of a preventive of damping. Seedlings should be pricked out directly they can be moved with a pointed stick in one hand and a small forked stick, for lifting them out with, in the other.

Propagating Chrysanthemums (*Journeyman*).—Several methods are adopted in rooting the cuttings, which should be about 3 inches long. The best system is that of placing them under hand-lights or in a propagating frame, placed in a house where a temperature of from 40° to 50° is maintained. These should be on the side stages, and as near the glass of the roof as possible to prevent the cuttings becoming drawn. Some growers root their cuttings in a cold frame, but they are more liable to suffer from damp; others in pots on shelves in an ordinary greenhouse, but in such positions they often flag very much. The cuttings may be inserted five or six round the edge of a 5-inch pot. Equal parts of light loam and leaf soil, with a free admixture of coarse silver sand, the whole passed through a half-inch sieve and thoroughly mixed, is the best compost. Sprinkle a little silver sand on the surface of the soil, to be carried down by the dibber for the cuttings to rest on, the rooting being quicker among sand. The soil should be pressed firmly round each cutting, particularly its base, and a gentle watering given through a fine-rosed watering can. Stand the pots on fine-sifted ashes for securing a cool moist foundation, and excluding air. The lights must be kept closed until roots are formed, with the exception that they may be taken off for an hour in the morning to allow for the dissipation of moisture, and in the evening the glass should be wiped dry. Shading will not be required. In about a month the cuttings will have rooted, when admit a little air by tilting the light slightly at first, and increasing until they can be safely removed. But little water will be required during the process of rooting, yet the soil must be kept sufficiently moist for the support of the cuttings or plants. Some growers prefer to root the cuttings singly in very small pots.

Compost and Manures for Chrysanthemums (*T. C.*).—A successful grower and exhibitor was favoured with the following analysis of the Chrysanthemum plant.

Potash	16.23
Soda	10.39
Lime	26.28
Magnesia	10.22
Iron	3.66
Phosphoric acid	19.52
Sulphuric acid	4.65
Silica	5.99
Chlorine	3.06
							100.00

Nitrogenous substances (albuminoids) ... 2.92

In preparing compost he cut the turf 2½ inches thick from an old pasture in the autumn; soil hazel or yellow loam, neither heavy nor light, stacking it grass side downwards, sprinkling on each layer of turves quarter pound of basic slag, 2 ozs. of kainit, and a small dredging of soot per square yard. Each layer of turves was so treated to the top of the stack, and in spring, when cut down for potting, chopping from top to bottom vertically, the whole was mixed together, to secure an even blend. The compost came out quite mellow, enriched, and free from pests. If the turf had much herbage the basic slag was increased to half pound. For summer use the grower used a mixture composed of

Bone superphosphate, dry and crumbling	5 lb.
Nitrate of potash, crushed fine	3 lb.
Sulphate of magnesia	1 lb.

This was mixed and kept dry. About a teaspoonful was blended with a handful of soil, and half of it applied to a pot after the final potting about every three weeks. Between times, if more vigour was needed, the plants were watered with nitrate of soda and sulphate of ammonia, half ounce to 3 gallons of water in alternate weeks. Thus the plants had a top-dressing of the mixture one week, the next a watering of sulphate of ammonia, and the following week of nitrate of soda, and then again the top-dressing. But of course he acted in accordance with the state of the plants, and avoided the error of overstimulation in the earlier stages, or, indeed, at any time. He mixed a little leaf mould and crumbled manure with the loam at potting time, exercising judgment in this and other routine matters, and, after all, sound judgment is more potent than anything else in growing fine Chrysanthemums.

Treatment of Eulalia japonica (Amateur).—Plants that died down after use and have since been kept in a cool house, may be removed to any structure where gentle warmth is maintained. They will soon commence to push up new growths, when the plants may, if increased stock is needed, be divided into two, three, or more pieces according to their size. These plants are most useful in 5, 6, and 7-inch pots, and grow freely in any rich soil—good loam, sand, and one-seventh of manure will suit them very well. If gentle bottom heat can be given them after division they will soon become established, when cooler treatment will suit them well.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state.* (L. R.).—1, Cox's Orange Pippin; 2, Golden Winter Pearmain; 3, Adam's Pearmain; 4, Hanwell Souring; 5, Hambledon Deux Ans; 6, Lord Derby. (C. H. S.).—1, Newton Wonder; 2, Warner's King; 3, Gloria Mundi. (F. W. H.).—1, Winter Nelis; 2, Easter Beurré; 3, Catillac. (G. H. F.).—1, Bramley's Seedling; 2, Wadhurst Pippin; 3, New Hawthornden; 4, Roundway Magnum Bonum; 5, unknown. (W. W. W.).—The Apples you send are all so inferior in quality that we are of the opinion they never could have had recognised names. (J. V. C.).—Pears: 1, Winter Nelis; 2, Easter Beurré. Apples: 1, Round Winter Nonesuch; 2, Lane's Prince Albert; 3, unrecognisable and worthless; 4, Blenheim Pippin.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (A. G.).—1, a fine form of *Cypripedium insigne*, but not, as you will observe, equal to the variety figured on page 5; 2, *Lælia autumnale*. (T. E.).—1, *Adiantum pedatum*; 2, *A. euneatum grandiceps*; 3, *A. Pacotti*; 4, *A. euneatum* var.; 5, *A. gracillimum*; 6, *Asplenium proliferum*. (Midlander).—1, *Abies Douglasi*; 2, *Taxodium distichum*; 3, *Retinospora plumosa aurea*; 4, specimen insufficient, possibly *Cupressus Lawsoniana erectus viridis*; 5, *Thuopsis borealis*; 6, *Thuia gigantea*. (P. F.).—*Cattleya Walkeriana*. (T. Taylor).—1, *Euphorbia splendens*; 2 and 3, send when in flower; 4, *Agathæa cœlestis*; 5, specimen withered, *Eupatorium Weinmannianum*; 6, a *Salvia*, flowers dead; 7, *Primula verticillata*. (Young Gardener).—Of the Ferns the Maidenhair is *Adiantum Pacotti*; the Gold Fern *Gymnogramma chrysophylla*; the finely divided frond, *Asplenium viviparum*; the other *Onychium japonicum*. The Orchid is *Zygopetalum Mackayi*; and the greenish white flower we think to be the parasitical leafless plant, *Orobanchë major*, but you give word of explanation relative to its habit of growth. We cannot name the specimens under numbers because these are coiled up inside the paper round the stems instead of being visible without untying the ligatures, which are made so tender by the wet moss that they tear at the slightest movement. Be so good as to read and follow instructions when you send other specimens to be named.

FEEDING SHEEP IN WINTER.

THE tendency nowadays is all towards early maturity; foreign competition has knocked all the profit off the four-year-old bullocks and the two-year-old wethers, and whether it be beef or mutton, all the cry is for small joints, not too fat, and plenty of them.

Twenty years ago good lamb was rarely seen before Easter, and never was it offered in anything but quarters, whilst a leg always had to be specially asked for. Now as early as May or even April legs and loins of well-fed and matured lamb are to be seen hanging in any butcher's shop; and can we wonder that the demand for mutton, fat and comparatively tough, unless well hung, should fall off during the summer months, if young and succulent, but nevertheless substantial, joints can be had for a very small increase in price? for 1d. or 1½d. per lb. would easily cover the difference.

Of course all sheep will not come to maturity at the same age, but it is merely a question of arithmetic whether a sheep is worth keeping at all over the age of fifteen months, except for breeding purposes.

In any case, when Christmas is turned, it is time that last year's

lambs, whether they are to go off fat from turnips or from summer pasture, or even to wait and make shearlings for Christmas again, should receive more forcing treatment than is always advisable during the autumn. Different classes of sheep are suitable for different purposes. The early maturing black-faced breeds, such as the Hampshire Down, will stand much more forcing and richer food than the heavier breeds up to a certain age, but we have found the latter make the better sheep at a year old, because they keep sounder on their feet.

The fact is sheep are like horses and all other animals, they cannot stand heavy feeding for too long a period, and wethers which are to be kept to twenty months old, must not be highly fed until they have passed the tenth month of their age. By high feeding we mean the use of foods calculated to form flesh and fat rather than bone. The mature animal must be built up first before it is fed; the young prematurely forced animal must be killed as soon as ready for market, for if allowed to pass the age of what we may here call premature maturity, there is a danger of deterioration, and a possibility of never reaching again the same standard of excellence.

It therefore behoves us at this period of the year to look carefully over our flocks, and see that we are not carrying over too long sheep which are now at their best, and that those which are capable of more improvement are pushed on to a profitable sale at the earliest opportunity.

So much depends on the staple food of a feeding flock that it is difficult to recommend a common ration of artificials. Where Turnips are plentiful, and form the chief food, a fair proportion of bulky dry adjuncts, such as dried grains or malt culm, added to cut (or chaffed) straw should still be used, particularly during periods of sharp frost, in addition to a due allowance of oil cake and corn.

For feeding sheep, with Turnips *ad libitum*, we think the following an excellent dry ration for every ten sheep per day:—

- 2 lbs. dried grains or malt culms,
- 3 lbs. decorticated cotton cake, ground fine,
- 2 lbs. beanmeal,
- 1 lb. linseed cake.

As much cut straw as they will consume is mixed with the above and 2 ozs. of flowers of sulphur per week. This ration may gradually be increased by the addition of more oil cake, but not more than 5 lbs. altogether, and perhaps the addition might be safer if given in the form of linseed. The mixture above mentioned works out to 0.8 lb. per head per day, and the 5 lbs. additional would bring it up to 1.3 lb. per head per day, and this is as much artificial food as a sheep will pay for, except in the case of pedigree rams, which we need not consider in connection with feeding for mutton only.

The artificials may be given all mixed together, but when the amount reaches 1 lb. per day it will be found better to give it in two meals instead of one, and the cakes are better given separately from the grains, culms, or beanmeal. These latter would be very useful to scatter over the cut roots left in the troughs in the forenoon. The careful shepherd likes to keep his feeding sheep in a quiet and satisfied condition, and when after lying down peaceably for an hour or two they get up and go to the trough, if they find something attractive there they eat for a few minutes and then lie down for another rest period; but if they find nothing to satisfy them they wander about, disturb others which are resting, and soon the whole fold is up and on the alert.

Some shepherds give the cake ration first thing in the morning, and there is good reason for this when the animals have been, as they are during the short days, without food for fifteen hours; but we should ourselves prefer to give it as the last meal instead of the first, especially in fine frosty weather, for the solid food with its percentage of oil helps to keep the body warm during the night, and besides this it prevents the sheep eating too many roots towards the close of the day. Roots which contain such a large percentage of water cannot be good for animals to sleep upon, and in this connection we must advise the shepherd or some efficient

substitute always to visit the fold about 9 or 10 P.M., not only to see that none are on their backs, but to set all up on their feet, and give them a turn round the fold. Lying still the whole night on cold or wet ground without moving is a fruitful source of ill amongst even such hardy things as sheep.

We have presumed that Turnips are plentiful and hay comparatively scarce. Where these conditions are reversed the dried grains or malt culms may be dispensed with, as good hay will answer the same purpose. The oil cake, however, should be a necessity, and the beanmeal discarded in favour of Barley or Maize—i.e., if the staple food of the sheep be hay consumed on grass. To sum up. The more roots the more nitrogenous foods and fat, the less roots the more carbonaceous foods, such as Maize or Barley, but good sound cake is always in the right place.

WORK ON THE HOME FARM.

The weather is still open. Christmas promised to be seasonable, but the frost was very temporary, and insufficient to have much effect on heavy soil. It is now as mild as ever, and ploughing goes on merrily where there is any left to do. We are ploughing close up behind the sheep-fold, and are thinking of cross-cutting fallows soon unless we have a change.

Of course there will soon be need to relieve the yards of a little muck, but we prefer to keep that work in reserve for frosty weather. The question is, Will there be any? Perhaps in April or May, just when it is not wanted.

We are scotching and trimming the various hedges, those next the fallows being done first; we can then plough round close up to the fence turning the furrow from it. A man sent round the field with a fork will soon shake the sod out further from the hedge, where it can be dealt with by the drag and harrows later on. After cleaning, the furrow may be ploughed back again to the fence. Field corners may be dug now, which could not have been easily done when the land was so hard and dry.

Wheats are looking fairly well, but larks are still doing mischief. We are afraid Wheat may lose root in early spring. When walking over it we find the land not solid enough, and the roller must be used at the earliest opportunity. Though it might not suit everybody, we should rather like a good covering of snow, and then a month's frost. More moisture is urgently needed, for springs are still low, and very unfit to meet another dry summer.

We have a man salving the ewes; he declares them to be rather low in condition, so we shall put them with the gimmer hoggs, and give them cut Turnips for six weeks. Ewes may easily be overfed before Christmas, but not after. If an ewe has a good back at lambing time she can well rear lambs, for there is some spare flesh to milk off.

REMARKS.

- 25th.—Fair, with some sunshine in morning, and bright night.
 - 26th.—Fair day, milder, with gleams of sun in morning; gale at night.
 - 27th.—Gale all day; fair early; spots of rain from 11 A.M., and incessant rain from 1 P.M., very heavy at 2.30 P.M.
 - 28th.—Rain till 2 A.M.; clear sunny day; moonlight night with halo.
 - 29th.—Dull almost throughout with frequent rain; gleams of sun between 2 and 4 P.M.
 - 30th.—Almost cloudless throughout.
 - 31st.—Fair early; dull with frequent rain after 10 A.M.
- A mild wet week completing a very mild December.—G. J. SYMONS.

BARR'S SEED GUIDE FOR 1899 IS NOW READY.

And will be Forwarded Free on Application.

BARR'S SEED GUIDE contains a Select List of the best Vegetable Seeds and most beautiful Flower Seeds. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. SENT FREE ON APPLICATION.

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS contains a liberal assortment of the following useful vegetables: Beans (Broad and French Beans), Beet, Borecole, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrot, Cauliflower, Celery, Colewort, Corn Salad, Cucumber, Cress, Endive, Herbs, Leek, Lettuce, Melon, Mustard, Onions, Parsley, Parsnips, Peas, Radish, Salsify, Savoy Cabbage, Scorzoneria, Spinach, Tomato, Turnip, and Vegetable Marrow.

Other Collections of Barr's Vegetable Seeds, 5/6, 7/6, 12/6, 42/-, 63/- and 105/-. These Collections sent carriage paid on receipt of remittance. Full particulars on application.

BARR'S CHOICE FLOWER SEEDS.—Our Catalogue contains a Select List of all the most beautiful Annuals and Perennials. Special Collections for all purposes, and many Sterling Novelties.

All Seeds sent Carriage Paid on receipt of remittance.

ANT. ROOZEN & SON'S SPRING CATALOGUE For 1899,

OF

Vegetable & Flower Seeds

AND

BULBS & PLANTS IS NOW READY.

Will be sent Post Free on application to their Offices at OVERVEEN, near HAARLEM, HOLLAND, or to their GENERAL AGENTS—

Messrs. MERTENS & CO.,
CROSS LANE, LONDON, E.C.

No. 968.—VOL. XXXVIII., THIRD SERIES.

NOVELTIES RAISED AT. WINDSOR AND OSBORNE.

It is Messrs. CARTERS' privilege to offer the following new and choice productions to the notice of gardeners and private cultivators.

BRITISH QUEEN MELON.

Raised and named by Mr. OWEN THOMAS, Supt. of the Royal Gardens, Windsor. Awarded the First-Class Certificate R.H.S. Pronounced by the Committee to be not only the very best white-flesh melon ever submitted, but the richest flavoured of any colour. Awarded the Gold Medal of the Royal Cal. Con. an. Society in association with other fruit exhibited by H.M. The Queen.

In sealed packets, price 2/6 and 3/6 each, post free.

ROYAL OSBORNE CUCUMBER.

A valuable cross between the Rockford and an improved type of Telegraph, raised and named by Mr. GEORGE NOBBS, Head Gardener to H.M. the Queen at Osborne. In our opinion it is one of the best all the year round varieties introduced in recent years.

In sealed packets, price 2/6 and 3/6 each, post free.

ILLUSTRATED CATALOGUES, POST FREE.

CARTERS,

The Queen's Seedsmen.

Only Address—

237, 238 & 97, HIGH HOLBORN, LONDON.

The 32nd Edition is Now Ready.

200 PAGES. 150 ILLUSTRATIONS.
PRICE SIXPENCE, POST FREE.
(By Parcel Post—it is so large).

EVERY AMATEUR SHOULD POSSESS A COPY.

CONTENTS.—The Best Seeds and Potatoes for Garden and Farm; also Descriptive Lists of Carnations, Chrysanthemums, Dahlias, Fuchsias, Gladioli, Herbaceous Plants, Pansies, Pelargoniums, Phloxes, Pinks, Pyrethrums, Roses, and Violas, with full Cultural Directions for each.

BLACKFORD.—“The postman with your Spring Catalogue and Competitors' Guide was my 'first foot' this morning. It is without doubt the best and most useful publication of any I come across, and should be in the hands of everyone possessed of a bit of garden ground. Thanks! Thanks! Thanks!”—J. McG.

DUNDEE.—“The woodcuts in your Catalogue are excellent, and altogether it is beautifully got up.”—A. H.

LEICESTER.—“I received your Catalogue with thanks. It is a very useful work for amateurs, and none should be without it.”—H. S.

WELLINGTON.—“I have to thank you very kindly for your beautiful Catalogue you sent me. It is the most compact and instructive Catalogue I ever read.”—J. P.

Journal of Horticulture.

THURSDAY, JANUARY 12, 1899.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

FRUIT OR WOOD.

NOTWITHSTANDING all that has been written on the pruning of fruit trees, it will always be necessary to write more, simply because the young and comparatively inexperienced will constantly be with us to need guidance in this important matter. Then there are, and it is hoped always will be, ardent amateurs who, becoming fascinated with the magnificent fruit they see at exhibitions, determine to become growers of equally fine or even finer samples.

It is not by any means certain that all of them will succeed in that object; indeed, perhaps the only element of certainty about the case is that the majority will not, and the probability is that not a few will find themselves far more expert in growing foliage and wood of robust character rather than blossom and fruit of the best quality; though some, contrariwise, will “rope” their trees with fruit in, so to say, double quick time, while producing little or no wood for extension, and think themselves very clever.

Nothing is easier than to grow far too much fruit and far too little wood on young trees on the one hand, and a forest of wood with a paucity of fruit on the other; and in the absence of knowledge on the theoretical principles on which action should be based, it would almost seem as if about half the people who plant, or are entrusted with the charge of trees, are prone to fall into one of those two extremes; one group not pruning at all, but leaving the trees to “Nature,” the other pruning too much, or at the wrong time, and relying on what they call “art,” and thus make a brave show with the knife.

It is scarcely too much to say that, with very few exceptions, both sections are wrong in their methods for building up trees that combine sound, healthy, thrifty growth with fruitfulness; and hence it is that we are obliged to see so many stunted, prematurely worn-out trees, where they are left to “Nature,” plus blundering in one case, and gross thickets of exuberant growths minus productiveness, where they have fallen victims to artistic pruning, or trimming them into shape, by men who are expert only in the prevention of fruit.

No. 2024. VOL. C., OLD SERIES.

How many thousands of good young trees have been ruined by rough or wrong planting and non-pruning, or "leaving them to Nature," as the planters erroneously think. As a matter of fact their action is in violent antagonism to Nature. When the raisers of thrifty young trees have prepared the land well for their reception, and by proper pruning formed them into shape by laying a good foundation of branches, the trees make admirable growth. They are thus sent from well-managed nurseries in that respect in the best of condition. If they were left undisturbed in the nurseries and had ample room for development it might be wise not to prune some at all beyond removing perhaps a few small superfluous branches entirely, and shortening the unripe tips of those intended to bear fruit. That would be the best plan if the branches were sufficiently numerous to form a good tree; but if too few it would be right to shorten them for producing more, and that is what a good nurseryman would do. In both cases "Nature" would be assisted—in the former instance to stud the healthy unshortened branches with blossom buds; in the latter to incite free, healthy, and, for the first season at least, blossomless growth.

But digging up the young trees, planting them, and then not shortening the long young branches, is quite another matter. This is not aiding Nature in the least, but the exact opposite, because Nature does not dig up the young trees and leave behind the greater proportion of fibrous roots that were necessary to support the rod-like branches. It is impossible, therefore, that the paucity of roots left can in any adequate way support them after the trees are replanted.

For producing free growth the first season the branches must be cut back in proportion to the roots which have been shortened—left behind in the process of digging up. This branch pruning will be to the extent of one-half, but more probably two-thirds, as equivalent to the loss of fibrous roots. The best time for cutting back the branches of newly planted trees, is not when all the buds are dormant, but when those at the extremities are elongating and on the point of unfolding young leaves. The lower buds will then be in a quiescent state; still the sap will be active, and the removal of the upper half or more of the branches will concentrate it on the lower buds, which will quickly start into growth. This was the practice of the old masters, who called it "flushing" the buds for forming a strong base to the wall trees, of which they were so justly proud. The young sparks of the present day think they can grow and train them equally well, but they can do nothing of the kind; they are more expert at spoiling trees, as was very truly pointed out by "A Nurseryman" not many weeks ago.

At present we come to this fact—if you want a free healthy growth of wood, cut well back the branches for producing it; if you want to see the branches of trees studded with bold fruit buds, the less of shortening the better, and then if the branches are thinly disposed, or not less than a foot apart, and preferably more, wood buds will be changed into blossom buds because they cannot help it. It is easy enough to effect such change, but difficult to transform a blossom into a wood bud. Such at least is the experience of—
AN OLD HAND.

IN THE DAWN OF THE YEAR.

WHEN we cross the threshold of a new year, Hope is our welcoming word. We look on the garden, not as it is now; we think of sunnier days, when flowers are no longer scarce; when they laugh in the sunlight, and breathe the summer air. But this word "Hope" is spoken with bated breath. We have had a mild winter; it cannot last like this until summer comes. We know that chill winds and keen frosts will come to check our flowers. Even now, though mild in the garden, the mountain which towers not far away is white with snow. True is it that the charm of the garden now is the promise it gives of the future. Yet it is no less true that even at this drear time we may glean pleasure. "Glean" we say advisedly, for no sheaves of flowers are there, but only stray treasures for the gleaner. It may seem scarcely worthwhile telling of these, yet to some they may give good cheer.

First must come the Snowdrop, called the "earnest of the year." Not yet have come the "Fair Maids of February," which in snowy sheets whiten many a park or lawn, or in the border contrast with the blackness of Mother Earth. They are hastening on, but dally still, for their time is only near, and has not arrived. Welcome will that time be, when, instead of a few of these pearly eardrops, we have them in phalanxes—an Amazonian army of loveliness. Look with me now at those in bloom. *Galanthus octobrensis* comes first. It is not well named; December is its usual month, and although a few flowers look now forlorn, several others are yet fresh and pure. There, too, is *Galanthus Elwesii*. From Grecian soil it has found its way to our northern isle, where it seems happy with us, though not with everyone. A shapely Snowdrop it is, fairly stout and strong. Here, again, is a plant of a selected variety of the Bithynian stock of *Galanthus byzantinus*. It seems, as it is understood to be, a hybrid between *Galanthus Elwesii* and *Galanthus plicatus*. With the flower of the first and the leaves of the second it is an interesting plant. Not all the bulbs of this Snowdrop give flowers so soon, for this variety was selected by our Snowdrop pundit, Mr. James Allen, from among many of later bloom.

The queen of the Snowdrop now is, however, Mr. Edward Whittall's newly found giant variety of *Galanthus Elwesii*. It may not always bloom so early in the season, but when it does it will always be welcome with its broad leaves, tall stems, and large flowers. If, as is said, the maiden of the end of this century is taller and more athletic than was she of its beginning, we may consider this new Snowdrop her representative in the maidenly possession. Another herald is there, too, but one of summer, which has either been asleep until long after the time of trumpet-call or has come untimeously. It is a flower of the large white Peach-leaved Bellflower, *Campanula persicifolia alba grandiflora*. Oh, foolish flower! Pretty it is though it has opened 'mid rain and frosty nights and all the discomforts of the season of the year. Its fate is no mystery to us.

"Fair-handed spring" is yet afar off, but the early Crocus accompanies the Snowdrop, though its deity, the sun, gives it few of his favours. Here is the bright orange yellow *Crocus vitellinus*, brighter than gold in the garden this gloomy day. Its roots and leaves have lured the alchemist to scorn, and have from earth and air with mysterious process drawn the cups of deepest gold. Though the sun smiles not, and they cannot open their bright chalices, these little sires are precious gems to us now.

In more Quaker garb is *Crocus Creweii*, with buff, dark purple lined cones, which grows close by; it wears for the sunlight. Its dress may now be sober and dull, but its inner beauties are great. When the sun shines brighter it will open its white saucers, zoned with gold and contrasted by the black anthers which are its most distinct feature. One or two more Crocuses there are now, and many are on the way to be ready to respond to the wooing of the January sun.

If the Almond is to the Mahomedans typical of hope, what to us lovers of the garden must be that little tree whose petals now begin to show? Long before the Almond it clothes its bare branches with flowers. It is a precious thing indeed which will open when we have just left New Year's Day behind. The tree is *Prunus Davidiana*, a variety of *P. persica*. The first flowers are bursting through. They are worth looking at even now; the white variety with its petals showing above the pale green calyx, and the bright red of the variety *rubra* showing through the brown-green of its protective covering. Heavy rains and clouded skies have kept back some of our early flowers, but the winter Heath, *Erica carnea*, has begun to show colour on its wax-like blooms. Soon it will be bright and ready for the first bee which ventures to wander from its hive.

One could tell of the pale gold of the Winter Aconite peeping through; of some other flowers, such as the Polyanthus or the Wallflower, which give us bits of colour now. One could tell of the greenery around, of Saxifrage, of Ivy, of Cotoneaster, or other plants whose leaves are green. One could tell, too, of the golden stars of the yellow Jasmine. Above all we could tell, did not space fail, of a rare Iris or two past, in bloom, or coming on, or of the many bulbous flowers which, with wondrous power in their delicate unfolded leaves, have pierced the soil in obedience to Nature's laws. The greenhouse may be gay, the garden dull, but its beds, its borders, and rockeries, are full of never-dying interest in the dawn of the year.—S. ARNOTT.

FORCING ROSES.

TO-DAY (January 3rd) I cut a number of really good Roses, and was struck with their beauty and delicate perfume when compared with the majority of flowers available at this season. After all, Roses take the palm at all times, provided the flowers are clean and fresh in colour. I note that a correspondent has been inquiring more than once upon how to force Roses successfully, and especially how to get them sufficiently matured to start into growth at the present date. I must confess to surprise that anyone should experience difficulty in getting plants ripened by the early part of the year. Even our plants in the open, their roots in wet soil, and the season very mild, are well matured, and have been for this two months past, so that I am sure there is something very wrong in the treatment if your correspondent fails to ripen them in pots, where he has the decided advantages of water control, and the fact that pot Roses have made the bulk of their growth before those in the open are barely on the move.

If one wishes for Roses at Christmas and January, they must select the right varieties. It is almost useless to try those with very double blossoms, although, in those cut to-day and previously, there were Jean Ducher, Maman Cochet, Catherine Mermet, and Bridesmaid; but in this case the plants have been well matured, and forced for several years in succession. Of course, as they are in full bloom now, they will naturally have made their second crop quite early in the season; for Teas in pots should be allowed to flower a second time the same season, in accordance with their natural habit outdoors. Most of the Hybrid Perpetuals, on the other hand, are better removed to another house, and the space occupied by a second set of plants. It seldom pays to keep the Hybrid Perpetuals for a second crop under glass during the same season.

The plants that are now in flower were housed early in November. They would have been under cover three weeks earlier had not the weather been so mild. After they had flowered the second time last season they were removed to a sheltered place outside. This was some time in May or June. By not overwatering, the wood left below where a flower was cut, and also that producing no bloom, got much harder and ripier than would have been the case if not fully exposed. It is true that most of the plants were active still, producing several small flowers and young growths from the point; but I would not have it otherwise, even if it were possible. We never see a Tea-scented Rose at complete rest, unless very severe weather has been experienced. Then why expect it during summer? The plants stood in this position until early in September, when they were turned out of the pots, as much of the old compost rubbed off as could be without seriously disturbing the roots, and repotted into a good and rich loamy compost.

It seems a rooted idea that no pot Rose must have its roots disturbed under any consideration, or the growths will go blind. This is wrong, and no doubt arose from the fact that if we are to get the best results from our most vigorous growers the season following their roots should not be disturbed. But the two cases were not quite similar. With our medium growers we prune back to ripe eyes, and cut away a considerable amount of the wood. In the other case we cannot prune without sacrificing the best flowering wood, and consequently if the roots are to develop the whole of the eyes upon long rods of growth, they must be more established than is necessary with weaker growers. Climbers in pots are generally repotted at the same time as the others, but they need quite different treatment during summer, and are simply repotted without removing much of the old compost. These will be alluded to again in due course.

When the medium growers are repotted they are stood on a fairly sheltered border, and frequently syringed if the weather is dry. This prevents wood shrivelling from the slight root disturbance. Three weeks or so afterwards the plants are pruned, but remain in the same position as long as the weather is mild. The fact of their being fairly ripe, the slight root disturbance, and their contact with fresh soil, induces new roots to form rapidly. All of us have noticed how very soon a Rose puts out new roots when laid into fresh soil. This is so, even in the dead of winter. How much more so during the genial days of autumn? It is self-evident that with only ripened eyes left on the plant, and the roots pushing into vigorous growth, the eyes must move as well. And they do. It is our place to see that this spurt of activity does not receive an injurious check. This is where so many fail. Remove the plants to cover as soon as frost appears, or even cold weather. As already remarked, the last autumn did not necessitate this until much later than usual, nor was there need of artificial heat for some little time after housing.

Early in December the plants had healthy young growths from 2 to 4 inches long, and were then hurried by a little fire heat; in fact, we endeavour from the first to bring them on as naturally as possible; and we never find full summer weather while the plants in the open are quite or nearly dormant. Yet so many introduce a ripe plant into an almost stove temperature before the sap has become active. A little thought would surely prevent this. I need not say that only the ripest and most promising plants are chosen for winter forcing, the others are saved to come on as a second and third supply.

Now to come a little closer to the point that I gather your correspondent finds some little difficulty in. After the later plants have flowered and been placed in the open they are treated the same as the first, except that they are not potted quite so early, and are housed in pits instead of remaining in the open again for a time. The pits are merely used to keep off excessive rains and the chilly weather; otherwise the treatment is similar, the Roses being taken to a temperature of 40° or 45° early in the year. This, together with the remarkable influence the sun has upon all plant life after the days have turned, causes healthy and strong breaks of new growths. I believe in working Roses in pots on much the same principle as we adopt with Tulips, Hyacinths, and other bulbs. We get some root action first here, and do not put the bulb into a greenhouse heat at once. Do we not find a steady root advance in the open before our Roses break into growth, and before early summer weather is experienced?

The general routine of culture under glass I will not dwell upon now; it has been given so often. But I do feel certain that most failures to force Roses early can be put down to the few errors of judgment I have endeavoured to point out.

The difference when growing climbers in pots lies in cutting them down as soon as the crop is over. Maréchal Niel and others seldom give us a second crop the same season, and it is well to secure more long rods of maiden growth for the next season. This is why the plants are kept under glass and fed freely until such rods are obtained, after which they are removed to the open to ripen and mature, ready for early forcing once more. If your correspondent has any further difficulty, and will give a description of it, as well as his treatment of the plants, I will gladly help him to the best of my ability, and when I say that fully twenty years ago I was fortunate enough to secure one of the R.H.S. medals at South Kensington for cut Roses grown in the winter, and have been more or less among pot Roses ever since, he will, perhaps, believe I have a right to the *nom de plume* of—PRACTICE.

SOIL ANALYSES.

YOUR Forest Hill correspondent, "H. H. R.," refers in the issue of December 29th last (page 500) to some observations of my own on the above subject in a previous issue. I had satisfied myself by experience that it was easier to lose money than make it by extensive series of soil analyses, and to found thereon a system of special manuring for various kinds of crops. After applying, on scientific advice, what were considered appropriate food materials for certain kinds of vegetables, fruits, and flowers, and finding that no small amount of time, with some money and reputation, was being wasted in the process, an escape was made from the fanciful routine.

Most of us are, I suspect, prone to indulge in imaginings even if they be vain, as mine has proved in respect to "H. H. R." I could not bring myself to think of him as a professional gardener, though I had an idea he might be something more—a philosopher learned in the sciences. I am surprised to learn on his own authority on page 500 that he is "no chemist." That being so, I am driven to the conclusion that he neither derives inspiration from practice in the garden nor from original scientific research.

Such men are often ardent lovers of gardening, and sincerely desirous of being helpful in it; and are, in my experience, just the men to think that wonders may be wrought as the result of acting in accordance with the revelations of soil analyses. I have not the smallest hesitation in saying that is a mistake. The greatest successes in cultivation have been attained without anything of the kind. If the soil must be analysed, to find what it does and does not contain, so must the plants and crops intended to be grown in it, or we should be "no forrader" in our dream of so-called scientific manuring; and then as the constituents differ in the same kinds of plants as grown in soils of diverse nature, where are we? Not in a flood of light, but rather in somewhat of a fog.

I have been fogged many times by scientific elucidations (?) and, rightly or wrongly, have arrived at this conclusion—namely, if a man cannot make the best of a garden in producing what is required to be grown in it without all the diving into the mysteries which men with a scientific turn of mind desire, that such man is not endowed with the instincts of a gardener. I have been what I once thought guided, but now call bothered, by numbers of analyses, and found them of no practical use, but, on the contrary, more or less bewildering.

In consequence of "H. H. R." quoting Cousins' "Chemistry of the Garden" as an authority on the subject in question, I obtained the little book. I expected to find in it analyses of various soils and plants, also advice given for adapting one to the other by the application of exact ingredients. I am astonished, after the references of your correspondent, to find nothing of the kind, and think I have discovered that Mr. Cousins has a more practical mind than his admirer seems to possess. What does the author say? Under the heading of "Plant Ash Fallacies" he says boldly: "Certain well intentioned persons have analysed the ash of some cultivated plant, or perhaps have consulted the monumental work of Professor Wolff, which gives the composition of the ash of hundreds of plants, and have then deduced from the figures set forth the ideal manure for the plant in question. This is a method based on the most egregious fallacies." What has your Forest Hill writer to say to that? or to this?—"To put it plainly, the plant ash is at the best but a general indication of the needs of a plant, and those who employ it for the practical instruction of the worker are indeed blind leaders of the blind." That is plain enough in all conscience, and I am not without evidence for sustaining me in the belief that it is correct.

I cannot resist saying that "H. H. R." appears an adept in taking ideas from books that he thinks favour his views, while ignoring statements in direct conflict with his theories. Only on one point does he make a practical suggestion, and this is the spending of 10s. on a "simple analysis" for testing the soil for lime, and adds that "the demonstration of this to the extent of half per cent. in the soil would justify the cost of a dozen analyses," or £6. Would it? Only if the fact could not be determined otherwise; but Mr. Cousins would settle the point with about two pennyworth of muriatic acid.

There we have the difference between a real scientist and a writer with the best intentions but "no chemist." If he had been gardener to a gentleman who had really very considerable knowledge of chemistry, and means for feeding plants and fruits scientifically, and had to feed them "to order" till ashamed of a brother blue apron coming into the garden, his faith would be somewhat shaken in the doctrine of simple analysis of the soil for making ignorant gardeners wise.—AN ENGLISH GARDENER.

[Yes; but not an ignorant one as judged by practical results over a long series of years.]

In these days of advancement in all the arts, it is no wonder that some of us gardeners are trying to keep up with the times. Lecturers are being scattered all over the kingdom, and when once they can induce us to take up the study of the property and composition of plants, soils, and manures, we in our rush for knowledge grasp at every straw that floats by us, feeling sure that if we can get hold of it, it will carry us to that mysterious land where we shall find what we seek. It is astonishing as we wander through text book after text book on agricultural chemistry, how rapidly our faith can change.

After passing through that desert of dryness which we find standing prominently before all the sciences, we find ourselves in a new world, a world stretched out before us containing a certain fascination, for in it we are able to learn some of the secrets of Nature, and are happy beings. As we wander on we learn how all vegetable life is built up out of soil, air, and water—all such simple substances when you understand them; and like the writers of the text books you feel you only want an analysis of your soil and plants, and some chemicals, and then you could grow plants wonderful to behold. Vain hopes of men are these. The analyses and the mixtures of chemical manures do not prove satisfactory to the test; and strangely our friend Jones grows finer fruit, flowers, and vegetables than we, and he—ignorant man—will have nothing to do with our mysterious world.

But onward we go, more reading of more text books, new ideas are being evolved in our minds, and alas! our first love is now slighted, for we find we have other things to consider connected with soils besides analyses, if we wish to grow good things. We are sorry for this, for we well remember in our early days what stress such and such a professor of the soil mysteries laid upon the analysis as being the very foundation of successful culture. His words fell deep, and now in our older days and up-to-dateness they have to be uprooted, for soil chemists now tell us it is not an analysis of the soil that we require, but an analysis of that portion which may be washed out of it with water and weak acids.

I have had my fill of soil analyses and the making of mixtures for plants, and now attach very little importance to the former, but then I am only one among the many, and my voice is lost amidst the multitude of believers. May they have good crops and a prosperous new year is the wish of—A WANDERER.

[We are bound to say that this "Wanderer" in search of knowledge has had much more than ordinary laboratory and actual cultural experience, and has found out how to succeed in growing produce for the million to a remarkable extent. We shall be glad if he has time to write again.]

CATTLEYA BOWRINGIANA LADY WIGAN.

THOUGH introduced from British Honduras by Messrs. J. Veitch and Sons so recently as 1884, the typical form of *Cattleya Bowringiana* is comparatively well known, and is highly appreciated for its many good qualities. In the "Orchid Growers' Manual," Messrs. B. S. Williams & Son say:—"It is closely allied to *C. Skinneri*, but we have found it a much freer grower and flowerer than that species. It is stated to have been found on cliffs by the side of streams near to waterfalls. In consequence, in its native habitat it receives a large amount of moisture. In cultivation it has been found necessary to give this plant an abundant supply of moisture, together with a free circulation of air." The flowers are rich rosy purple in colour. It is in colour alone that the variety *Lady Wigan* (fig. 5) differs from the type. The sepals and petals are lilac with a rose suffusion; the lip is reddish lilac on the front lobe, velvety crimson in the centre, with a pale primrose throat. When shown at the Drill Hall on November 8th by Mr. W. H. Young, Orchid grower to Sir F. Wigan, Bart., East Sheen, an award of merit was recommended by the Orchid Committee.

CYPRIPEDIUMS AND THEIR CULTURE.

RANKING as they do amongst the most popular plants in the Orchid family, *Cypripediums* deserve, and from many persons receive, the closest and most skilful attention. For the comparatively small grower they are particularly valuable, as with a judiciously chosen selection it is quite possible to have a few plants always in flower, and these last a remarkably long period, either on the plants or cut for placing in vases and other suitable receptacles. Take, for example, the well-known *Cypripedium insigne*, and think of its value during the months of winter, when choice flowers are almost invariably scarce. In it we have a plant that will, year after year, produce in November and December scores of flowers, provided reasonable attention be accorded to it. For the greenhouse, the conservatory, or the room it is alike valuable, and such are the variations in colour that it never fails to receive admiration from all beholders. But it is not proposed in these notes to deal with *C. insigne* alone, but to give a general survey of the genus, in the hope that the remarks may be helpful alike to the owner of a large collection as to the cultivator of only two or three dozen specimens of one or more kinds or varieties.

To grow a varied collection of *Cypripediums* two houses are necessary, one that can be maintained at a stove temperature, and the other at a cool intermediate heat, and it is immaterial in what form the structures are built, so long as the heating and ventilation arrangements are perfectly efficient. Then, too, they must be drip-proof, with top and bottom ventilation, the air from below being admitted direct to the pipes so that it becomes warmed before it reaches the plants, for no side lights must be opened to admit cold draughts. It is said that heat is life, and to some kinds it may be so, but to others it is quite the reverse. The stove should be so equipped that 60° can be maintained in cold weather, though when the temperature outside is excessively cold a fall of 2° or 3° will do no harm. In the summer a temperature of 70° at night will not be prejudicial if abundance of atmospheric moisture is provided, but a hot dry atmosphere must be avoided. The other structure should be so arranged that 55° in the winter can be commanded, with a rise of 5° or 6° in the summer months, and here again an arid atmosphere must not be tolerated.

To simplify matters in dealing with compost, the family may be divided into three sections:—1, the niveum section; 2, the tessellated leaved section, which is well illustrated in *C. Lawrenceanum*; and, 3, the green leaved section, and the latter as being the largest may be dealt with first. Many of them will grow in almost any kind of soil, but I have yet to learn that there is economy in using a poor soil at the outset. It is therefore our practice to employ two parts of peat, broken into good sized lumps, taking out as much fine as possible; one part of sphagnum moss picked clean, and one part of best yellow loam, taking out the fine in the same way as with the peat. These ingredients thoroughly incorporated are used as rough as possible, and the potting is not done too firmly. A slight elevation above the rim of the pot is all that is desirable. For the tessellated leaved section I invariably use equal parts of peat and sphagnum moss. In dealing with the niveum section we come to the one that is the most generally unsatisfactory. A mixture of two parts of peat and two parts of loam, prepared in the same way as the others, with a sprinkling of coarse

Bedfordshire sand, and say, one-sixth part of limestone seraps, has been found most satisfactory. For all sections pans and crocks must be scrupulously clean, and one of the most important points in the culture of these plants is an abundant supply of water when they are growing strongly, and are in vigorous health, and it is therefore necessary to afford as nearly as possible perfect drainage. The material

FIG. 5.—CATTLEYA BOWRINGIANA LADY WIGAN.

used must be so placed that water applied will pass rapidly away, and should from half-way to two-thirds fill the pots. The amount will vary according as the plant is a strong or a feeble rooted one.

Unlike many Orchids *Cypripediums* have no pseudo-bulbs in which to store food, and consequently cannot withstand drought. There must be no lack of water, though on the other hand the compost should never reach saturation. Naturally the amount of water will largely depend on the compost in which the plants are growing; the heavier this is the less water the plant will require, and the reverse. Personally I am firmly of the opinion that the great secret of plant cultivation lies in the proper administration of water, or in other words having a thorough grasp of when to apply and when to withhold. As a matter of fact there is as much difference in the highly finished touches of one of our finest artists and in the veriest daub one ever saw, as in the result achieved by the man who waters his plants properly, and one whose application lacks common sense and judgment. It is the power to concentrate the mind on apparently small things that leads to success in the greater, and for this reason I wish to forcibly impress the importance of careful waterings as well with *Cypripediums* as with any other plant in cultivation.

As these plants are essentially shade loving, if the sun shone directly upon them for any length of time the leaves would soon be disfigured by scorching. Means must therefore be taken to provide shade. For this purpose a raised blind or blinds of laths is the most satisfactory, as while breaking the direct rays of the sun, it admits a certain amount of light, and also allows air to pass freely between the blind and the roof of the house. The necessity of the closest observation of the individual requirements of each plant cannot be too strongly impressed on the cultivator, as experience teaches that some which would fail hopelessly in strong light would luxuriate in a shady corner. For example, neither *C. superbiens* nor *C. Sehlinii* will tolerate strong light. Equally as important as the points that have been adverted to is the ventilation, to which the closest attention should be paid. The necessity of avoiding draughts has already been briefly referred to, but the other extreme of not admitting fresh air at all is equally disastrous to plant life.

It should always be borne in mind that plants are living things that must be rationally treated. In admitting air do not use the top ventilators more than is necessary, as these allow the moisture to escape. A little air may be constantly admitted through the ventilators in the wall beneath, as previously recommended, but these should be open half inch only in cold and windy weather. As perfectly developed leaves are the main source of strength in these plants every possible means should be taken to preserve them in health. Broadly speaking, they are the lungs of the plant, and as such must be kept free from impurities. It is obvious that when the pores are full of dust they cannot perform their proper functions, and the plant suffers

immediately. Cleanliness is one of the greatest aids to successful plant culture, as it encourages the leaves to do their work, and it is certain that periodical sponging with a very weak solution of some approved insecticide is more than repaid by the increased vigour and health of the plants being dealt with. Many cultivators have doubtless been, as I have, called upon to take in hand a collection of dirty plants, and they will know the worry and disappointment that are incumbent upon such a task. Energy and perseverance are, however, all-powerful, and in skilful hands the recuperative powers of neglected plants are nothing short of remarkable.

Whilst healthy *Cypripediums* have few enemies, the name of the pests that attack weak plants is legion. No doubt everyone has observed how an unhealthy plant, like an unhealthy person, seems to be heir to all sorts of ailments, and the weaker the plant the more disastrous will be the effects of the attack. The pest most to be dreaded is black thrips, as the foliage is so soon disfigured; but if the atmospheric moisture and damping of the surfaces are properly attended to it will not cause much trouble, and should it show itself, one or two operations with the XL vaporiser will usually prove effectual in destroying it. Scale of various sorts will sometimes be found on the plants, but if the sponging is done as suggested, there need be little fear of serious damage. Woodlice, snails, and slugs are fond of young roots, and sometimes flowers, and are most readily trapped in Potatoes, the centres of which have been hollowed out. Cockroaches and crickets have eaten the edges of the leaves, and also the flowers, and must be eradicated by one of the several advertised remedies. Syringing ought not to be practised, as the water often gets in the young growths, and causes them to decay.

To name all kinds and varieties would be an impossibility, but I will enumerate a few, and suggest in which house they are likely to do best. For the stove take the *niveum* section in its entirety—viz., *niveum*, *bellatulum* and its variety *album*, *Godefroyæ* and its variety *leucochilum* (fig. 6), *concolor*, and most hybrids in which either of these species is a parent. In addition to these there are *Chamberlainianum*, *ciliolare*, *Curtisi*, *Haynaldianum*, *Hookeræ*, *lævigatum*, *longifolium*, *Lowi*, *Mastersianum*, *Rothschildianum*, *Sanderianum*, *Stonei*, and many of the *Selenipediums*, and also hybrids in which any of these species

FIG. 6.—CYPRIPEDIUM GODEFROYÆ LEUCOCHILUM.

are parents. The majority of those named will exist in the intermediate house, but as time is money, and many of them will grow much faster in the warmer structure, the cultivator must use his discretion, and place the plants accordingly.

Strides made in the collection of no class of plants have been so rapid as with *Cypripediums*, and I recommend to all plant lovers about to commence the cultivation of Orchids to try a few of them, as the plants are of the easiest cultivation, and last in bloom over a very long period; while to those who like subdued and refined colours nothing could possibly be more pleasing.—J. BARKER, *Hessle*.

CYPRIPEDIUM INSIGNE.

WHAT a useful plant this is for supplying cut flowers at this season of the year, and it is because we have realised its great value I am prompted to send a few facts that may prove interesting to my fellow readers. From one plant in a 12-inch pot we have taken fifty-two flowers, and from six plants in 9-inch pots the number of flowers have been twenty-five, thirty-six, forty, thirty-two, thirty-six, and thirty-six respectively, or a total of 257 from the seven pots. We also have three plants in 48-pots carrying eighteen flowers in the aggregate, and I venture to think these results very satisfactory.

It is now four years since the large plants were placed in the pots they now occupy, in a compost of turfy loam and peat, chopped sphagnum, coarse sand, pieces of broken soft brick, and charcoal. Last season we had seven twin flowers, the previous year eighteen twin flowers, but this season not one twin spike has been produced. This would lead one to think that a free root run is more conducive to the production of twin flowers than well-nourished plants in a root-bound condition. I am under the impression that I do not apply water so freely as some do, and as a consequence the plant food is more concentrated, hence their floriferousness. Our plants from October to May are given an intermediate temperature, while the other portion of the year they spend in a Peach house (not forced) or a span-roofed cold frame thinly shaded.—THOS. CROSSWELL, *Homewood, Beckenham*.

[The photograph sent with the above notes represents an admirably grown plant of an excellent variety, but it cannot be reproduced satisfactorily.]

THE CRYSTAL PALACE FRUIT SHOW.

"DON'T you think something should be done to help to arouse more public interest in this annual show?" said a friend to me the other day. Well, I am entirely of that opinion, and have for some time thought that, in spite of all that has been attempted and done, public interest in fruit culture is in this country at a low ebb. When I think of what public attention is bestowed on sport, and how little is given to such matters as fruit culture, I think of those lines which Shakespeare put into the mouth of the fallen cardinal, "Had I but served my God as diligently as I have served my king He would not have left me in my grey hairs to perish."

It will be a sad time for Great Britain if in years to come her people should have to paraphrase that bitter lament, and find cause for regret that more attention had not been given to practical good than to childish play. It is a long time yet to the next show, which will be held at the close of September next. Yet time flieth fast, and any arrangements needful for getting more of publicity and notoriety attached to the show need to be made in good time.

Some years ago, in the palmy days of the international Potato exhibitions, it was not difficult to secure the attendance of the Lord Mayor of London and the Sheriffs in state, with a big following. There seems attached to visitations of public men or prominent officials to shows a degree of publicity not commonly found when no such visits are arranged. To the general public a fruit show at the Crystal Palace is but an ordinary occurrence, few realising that it is the product of a great home industry, that it represents food of the most valuable and healthful description, and that it is also an industry which it is at once desirable greatly to improve and widely extend.

I do not assume that the Lord Mayor or the City Sheriffs are the only or the most fitting persons to invite to grace the opening of the show. We have noblemen and gentlemen, occupying distinguished positions, whose lives and acts are practically public property, who have the interests of fruit culture at heart, and who would certainly secure at a show of this nature a great following. The primary object of the exhibition, and of all associated with it, would be less the mere awarding of money prizes or of winning them, but rather creating a fine demonstration of British fruit, with the view to secure for it wider culture and a greatly extended demand.

The dropping out of the conference last year seemed to be a mistake, and it is hoped one, not necessarily for each day, will be arranged. But the Palace authorities should be invited to place a convenient room at the disposal of the R.H.S. for the purpose. Something better and less noisy than was the barn in which one or two previous conferences were held, and the subjects chosen for papers should be severely restricted to one per day. Papers as a rule are far too long. The readers have been given much rope, and in a spirit of kindness, in which, of course, there is no egotism, they proceed to use it by strangling the conference. Papers should not exceed twenty minutes' duration, allowing ample time for their discussion, and chairmen should be severe in keeping speakers closely to the subject in hand.

If subjects are wanted we can find them in "How best to promote the culture of Apples and Pears for market purposes;" "How best to place fruit into commerce to meet public requirements;" and "How best to develop the existing demand for fruit and its consumption." Thus in these three subjects we deal with the

primary hardy autumn fruits for culture, marketing, and expansion. Papers on these subjects should be sought for a little outside the general reach of readers. Surely there are others willing to furnish them beside the few who constitute generally the R.H.S. stock in trade of readers of papers.

Turning to the show itself, it will be well worth the consideration of the Council whether more effect cannot be obtained from a closer arrangement of the tables. Not only effect but interest is much lost when a show is so widely distributed. Still farther, it is so difficult to follow the run of the classes, of which there seem to be too many, especially of the single dish ones, of which at least a score might be lopped off with advantage. It is folly to offer prizes for varieties that are seldom represented by but two or three dishes. Even of very popular Apples it does not follow that classes should be made for them every year, if there be other good varieties generally grown that get left out in the cold.

In arranging the single dish classes, whilst good reputed popular varieties, that have well stood the test of time, should be kept well before the public, yet some others as good, perhaps better, should be occasionally noticed and encouraged also. Specially must care be taken to keep the schedule from being a trading compilation. The object of the show is less to develop novelties, which growers are at liberty to do to their utmost in their own collections, than to show to the public, and especially to the consuming public, what fine varieties we have in cultivation, and how superbly they can be produced. Very much might be done to make the show more attractive by introducing small plants freely about the tables, and by dividing sections or classes with small groups of cut flowers. But whatever is done should be done with a will, with full resolve to "boom" the show and fruit culture, and compel interest and patronage from the public at large.—A. DEAN.

AMERICAN BLIGHT AND NURSERYMEN.

MANY gardeners know what a troublesome pest American blight is when it gets an extensive footing on Apple trees, especially on those of considerable size and age. A very common way by which this pest is introduced into gardens and orchards is with consignments of young trees from nurseries. I have scarcely, if ever, received a number of trees from a nursery without some of them being affected with more or less of blight. If only one in a consignment be infested it is more than likely that the foe will spread over the remaining trees. In the autumn of 1897 I had an experience of this sort.

My present object is to refer to how I have got rid of the pest, and to make a suggestion to nurserymen that I think would be a safeguard to themselves, but especially to their clients. I first washed the roots of the trees with clean water to free them from all soil and any insects that might be burrowing. The trees were then thoroughly moistened through a syringe with a mixture of three wineglassfuls of petroleum to a gallon of soapy water, and in two or three minutes syringed with clean warm water. The insect vanished instantly under the petroleum bath, and I have never seen anything of it since.

My suggestion to nurserymen is, I think, one that is quite practicable. It would increase their reputations, save gardeners some trouble, and, I think, be a means of staying the spread of blight if, when trees were being lifted in the nurseries, a piece of isolated ground were set apart on which any affected trees could be "heeled in" till it were convenient to deal with them, instead of sending them away in the heart of a package of clean ones. I conceive that it might be inconvenient to deal with them, as I have described, in the bustle of the despatching season, but they could be dealt with when it was over. I feel certain that what I have recommended as an application is a complete remedy, and the tax on the nurseryman would not be great.

I was very much interested on visiting a garden a few weeks since, and inspecting a number of espalier Apple trees, most of which were almost covered with blight. They are trees, I should say, fifteen or more years old. There were a few varieties amongst them that were all but entirely free from the insect; yet in several cases the branches of the foul ones and clean ones were running side by side—in fact, fastened with the same ties. On asking the gardener if the clean ones always remained clean, his answer was that they did.—DAVID THOMSON.

[A case is recorded in the *Journal of Horticulture* of a nurseryman, on discovering some American blight (which was introduced by certain varieties of Apples) in his collection, employing a boy whose first morning's work throughout the spring and summer was to search for the blight and with a brush apply a strong yet safe solution of Gishurst compound. In this way the pest was extirpated. We believe our chief nurserymen are most careful not to propagate this great enemy of Apples. We have recently seen a number of young Apple trees uprooted and burned because of the infestation. The trees were a "cheap lot," obtained from a local market. Mr. Thomson's effective winter mixture would not be safe to apply to trees in summer.]

WEATHER IN LONDON.—From Wednesday until Saturday of last week the weather, though dull and cold at times, was open and, for the first week in January, very mild. On Saturday there were heavy showers, but Sunday and Monday were characterised by brilliant sunshine, the latter day being quite warm. Tuesday was showery in the morning, with hail and a drenching rain towards ten o'clock at night. Wednesday was bright, with showers at midday.

WEATHER IN THE NORTH.—The closing days of the year were marked by 6° of frost on the 30th, and 8° on the 31st, followed immediately by thaw. There were again on the 7th inst. 8° frost, and 6° on the following night, rapidly giving way to rain. With these exceptions the record of the past two weeks has been continuous gloom, fog, and wet. Tuesday morning was dull, with thermometer at 42°.—B. D., *S. Perthshire*.

GARDENING APPOINTMENT.—Mr. Thos. Harris, for two years with Messrs. J. Laing & Sons, previously seven years gardener at Ashby St. Ledgers, Rugby, has been appointed head gardener to A. H. Harman, Esq., Lower Greyswood, Haslemere, Surrey.

PETERSHAM COMMON.—The Board of Agriculture, in response to a memorial, has drawn up a scheme in respect of Petersham Common. This provides that the common shall be regulated and managed by the Corporation of Richmond, who are empowered to execute drainage and other improvements, to plant trees and shrubs, and render the ground more pleasant for recreation and exercise, but are inhibited from doing anything that shall otherwise alter its natural features or interfere with free access to every part. The Richmond Town Council are also deputed to frame bye-laws for the regulation of games and of assemblages of persons thereon.

DRILL HALL DISPLAYS.—When in past seasons one has read in our Journal that the various firms who make a speciality of growing the Primula, Cyclamen, Cineraria, and other florists' flowers have had such grand displays at the R.H.S. Drill Hall meetings, a feeling of regret at not being able to see them is often expressed. I think if the large firms who cultivate these flowers so well were to advertise when their specialities were likely to be seen at the Drill Hall it would give those interested the opportunity of seeing them. I am aware that such intimations have been given, but very rarely. Of course we are cordially invited to "come and see" the flowers at home, but when the naturally desired "order" cannot easily be left behind one feels a little reluctance in spite of the invitation.—A BECKENHAMITE.

THE SECRETARYSHIP OF THE ROYAL GARDENERS' ORPHAN FUND.—Rumour, as might be expected, is busy, ubiquitous and perhaps exaggerated, in regard to the vacancy which is created by Mr. Barron's retirement. It is to the effect that there are hundreds of applications from all sorts and conditions of men, not to say lady gardeners. The army, navy, church, law, press, as well as the gardening fraternity, are all said to be represented. If all is true that is heard on the matter, the special Committee appointed to consider the applications have no light task before them. For ourselves we hope that, as the inception of the Fund must be credited to gardeners, someone intimately connected with gardening will be found to possess the requisite qualifications for the position. On one point at least there will be unanimity—namely, that the health of Mr. Barron will be greatly improved and eventually completely restored by the rest from duty that he deserves so well.

— Is the post soon to be vacated by Mr. Barron to be filled by the Committee, or at the next annual meeting? This question arises out of the somewhat vague wording of the advertisement for a Secretary. Another and pertinent question is the following:—Is the personal canvassing of individual members of the Committee by prospective secretaries quite in order or politic in a charitable institution above all others? It is an open secret that this has been freely done. Those who have thus acted are perhaps oblivious of the fact that in many similar advertisements canvassing the Executive is held to be a direct disqualification. Why not so in the case now under consideration? If the election is made at the annual meeting, it is hoped that it will be by ballot.
—ANNUAL SUBSCRIBER.

FROZEN SEEDS.—Experiments with plant seeds subjected to extreme cold have shown that the power of germination is not destroyed, but merely suspended by the cold. By the use of liquid air, seeds of Barley, Oats, Squash, Cucumber, Peas, Sunflower, and some other plants, were recently kept for 110 hours at a cold of 183° to 192° Centigrade. They were then carefully and slowly thawed for fifty hours. After sowing (says an American contemporary) they germinated as well as if they had not been frozen.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We remind our readers that the sixtieth annual general meeting and election of pensioners of this Institution will take place at Simpson's, 101, Strand, London, on Thursday, January 19th, at 3 P.M., and that the usual annual friendly supper will be held at the same place and on the same date, at 6 P.M., when the chair will be taken by Mr. George Monro of Covent Garden, member of the Committee of Management. Those friends who desire to be present on the occasion should intimate their intention to the Secretary on or before Monday next the 16th inst., at the offices, 175, Victoria Street, London, S.W.

ROYAL METEOROLOGICAL SOCIETY.—The annual general meeting of the Society will be held, by kind permission of the Council, at the Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 18th inst., at 7.45 P.M., when the report of the Council will be read, the election of officers and Council for the ensuing year will take place, and the President (Mr. F. Campbell Bayard, LL.M.) will deliver an address on "The Government Meteorological Organisations in Various Parts of the World," which will be illustrated by Lantern Slides. The above meeting will be preceded by an ordinary meeting, which will commence at 7.30 P.M.

ALOES.—It is fortunate that so many members of the above S. African family open their flowers in the winter, the large spikes of gorgeous blooms making a striking feature when most things are at rest. In the succulent house at Kew a number of plants are now at their best, and quite a nice show is made. Among the most noticeable are *A. fruticosa*, with scapes 2½ feet long, bearing dense heads of orange red flowers, 8 inches long. Several plants of *A. pluridens*, with branched racemes, the flowers varying on different plants from yellow to red. The sturdy glaucous, purplish leaved *A. purpurascens*, with a strong spike of red green-tipped flowers. *A. brachystachys*, with long, slender spikes, and *A. frutescens*. The latter is represented by a particularly fine specimen. It is one of the smaller leaved section, and branches freely to form a large bush; on this a large number of flower heads are produced on scapes 2 to 2½ feet long. Besides these a number of plants are flowering in the Mexican house; these are planted at the base of pillars, and are seen to the best possible advantage. *A. arborescens* and *platylepis* are a fine sight; several large, many-branched racemes of bright red flowers are now at their best, the flowers being shown off finely against the light colour of the building. A glance at the strength of these flower heads is enough to show the advantage of the planting out system.—D. K.

SPADE LABOUR.—In the extract from Mr. W. Roupell's paper on "Suburban Fruit Growing," published in your last issue, there is special reference to the need of training youths in the use of the spade in gardens. No doubt the use of the spade or fork, wherewith to trench, ridge, or dig, is not popular with those young men who regard all work outside of houses as menial and vulgar; but a pretty sort of head gardener will be ultimately made who has not when young learned to use the spade. When I read this little reflection of Mr. Roupell's, my mind was naturally carried to the work being so largely done in Surrey in connection with boys' continuation school gardens, under the County Council, where hundreds of youths are annually being taught, not only how to best handle or use spade and fork, but also to utilise them in the cropping of small areas of ground profitably. Lads so instructed prove to be very valuable helpers when they drift off into private, market, or other gardens somewhere, as many of them do. No one more than Mr. Roupell would be gladdened to see these lads at the work on summer evenings. We want an army of diggers and forkers in this country, because it is only through such agency that soil can be made fully capable of giving forth of its productions. I have regretted to learn that in some places, because lads are not regarded as eligible for this training until they have left school, the Educational Department somewhat harshly interposing, that some groups of gardens have to be closed, as boys seem so much sought for they are found employment the moment they leave school, and school horticulture is of little value. No better authority for the promotion of gardening amongst the young exists than the County Council.—D.

— *HELIOPHILA SCANDENS*.—A plant of this S. African Crucifer is now in flower in the succulent house at Kew. It is a climbing plant with small, dark green leaves, and produces loose racemes of white, Wallflower-like blossoms in great abundance during November, December and January. It is an easily managed plant, and might be used more extensively than at present, both as a climbing plant for the roof, or a pot plant for the cool greenhouse. It will root from cuttings, and almost any ordinary potting soil is suitable for it. Plants which flower so freely as this, at a time of year when greenhouse flowers are scarce, are worthy of prominent places.—KEWITE.

— **FRUIT EVAPORATION**.—There is a big outlet in the fruit business awaiting development in India in connection with the evaporation process. Not fruit drying, but fruit evaporation, because the difference between the two processes, both as regards quality and cheaper working, is very marked. In a recent pamphlet issued by the Department of Agriculture at Washington, the great progress made of late years in America in this connection is described. In Prunes alone it is stated that 2,914,599 lbs. were imported in 1888. In 1896, however, the Californian product was estimated at 55,200,000 lbs., and Washington, Oregon, and Idaho also largely engaged in Prune culture and evaporation, so that last year the product of American orchards exceeded 100,000,000 lbs. of dried Prunes. The increase of home production has been noted in the decrease of imports, which had fallen in 1897 to 736,978 lbs.—("Indian Gardening.")

— *PYCNOSTACHYS URTICIFOLIA*.—At this season of the year this plant comes in very useful for the intermediate house, as the flowers—besides being freely produced—are of an uncommon colour. It is a tropical African plant, and at first sight might be taken for a *Salvia*. When growing strongly, the Nettle-like leaves are often from 8 to 9 inches long by 7 inches wide at the base. The flowers are a rich, dark shade of blue, and are borne in dense conical racemes from 4 to 6 inches long, from the points of all the main and lateral branches. They commence to open about Christmas, and are in good condition during January and February. It is not a difficult plant to manage. Cuttings should be rooted in spring and be kept growing all the summer, the same treatment being given as is accorded to *Chrysanthemums*. When young they should be stopped frequently; by this means good bushy plants, in 8 or 9-inch pots can be had. After being grown outside all the summer they should be put into a cold frame in September, removing to an intermediate house as the buds begin to show. If planted out in a warm greenhouse growth is more vigorous, and if the room can be given plants 10 feet high with an immense number of flower heads can be had in a year from cuttings. A number of plants may now be seen in flower in the Mexican house at Kew.—W. D.

— **EMIGRANTS' INFORMATION**.—The January circulars of the Emigrants' Information Office and the annual editions of the penny handbooks show the present prospects of emigration. The notice boards are now exhibited, and the circulars may be obtained free of charge, at more than 300 public libraries throughout the country. In New South Wales matters relating to trade, labour, and industry are improving, and land settlement is increasing. The dairying industry is largely on the increase, and many new factories are being erected. The number of unemployed throughout the colony has become much less; scrub cutting at the West Bogan is almost the only Government work now being carried on for the benefit of those out of employment, the average wages there being 5s. 6d. a day. But the effect of the long drought, and of serious disputes between capital and labour, have made employment in many cases precarious. In Victoria farmers would do well. In South Australia a Government Labour Bureau has just been established for the purpose of facilitating the obtaining of employment. The Bureau is situated in Victoria Square, Adelaide, and branches may be established elsewhere. In Queensland, notwithstanding the late severe drought, which caused great losses in the western and central districts, settlement on grazing farms by practical men is steadily progressing, especially in the west and the north-west; the tick disease in the north has become much less prevalent. There is a general demand throughout the colony for ploughmen and other farm labourers. In Western Australia there is a good demand for farm labourers in many parts of the south-west. In Tasmania the demand for most kinds of ordinary labour is increasing there as the mines develop, and men able to take up and work a few acres of land will get a good price for vegetables. In other parts of the colony there is no general demand for more mechanics or farm labourers. In New Zealand ordinary labourers find plenty of work in country districts at this season of the year. In Cape Colony and Natal there is little demand for mechanics or labourers at the present time.

— **A SCOTTISH WEATHER GRIEVANCE**.—A Lothian correspondent expresses the hope that dwellers in the South are enjoying more seasonable weather than that by which northerners are, as he says, "tormented," and his outburst of grief culminates in the exclamation, "No ice for storing, and no curling!" It must be very sad for the fine old gardener, but perhaps the weather will change before June, so that he may have a hit off and be happy.

— *STERNBERGIA LUTEA*.—I send you a few flowers of *Sternbergia lutea*, to show how well it withstands the rough weather of the last month. It was on New Year's day by far the brightest flower in the garden in the open air, and will be for some time to come, as I find there are yet quite small buds to open. The bulbs were not planted until October last, which of course accounts for its flowering so late, its usual season being September and October. Judging from the results of this season's planting a succession of flowers may be had by planting at intervals.—J. H. LANE. [The flowers were very rich in colour, and must have materially brightened the already beautiful garden of Mr. Elwes at Colesbourne.]

— **COLONIAL PARCEL POST**.—The postage to be prepaid on parcels for Antigua, Ascension, Bahamas, Barbadoes, British East Africa, British Honduras, Beyrout, Ceylon, Constantinople (by direct steamer), Cyprus, Dominica, Falkland Islands, Gambia, Gibraltar, Gold Coast Colony, Grenada, Jehore (via Singapore), Lagos (Africa), Malta (by direct steamer), Montserrat, Nevis, Newfoundland, Niger Coast Protectorate, Niger Territory, St. Helena, St. Kitts, St. Lucia, St. Vincent (West Indies), Sarawak, Seychelles, Sierra Leone, Smyrna (by direct steamer), Straits Settlements, Tobago, Tortola, and Trinidad, is now for each parcel weighing not over 3 lb., 1s.; over 3 lb., but not over 7 lb., 2s.; over 7 lb., but not over 11 lb., 3s. A similar charge will be made in the postage on parcels from these places for the United Kingdom.

— *CUPRESSUS LAWSONIANA* FOR HEDGES.—The Oregon, or white Cedar (*Cupressus Lawsoniana*), is remarkable for the number of its varieties. In its native land it attains great dimensions—150 feet in height and 18 feet in girth, more or less. The wood is white and fragrant, and much in demand. In this country it is used chiefly for ornament and for hedges. For the latter purpose trees 5 feet or 6 feet in height, and planted at 3 feet or 4 feet distances, a useful hedge can be obtained almost at once. The root fibre is usually plentiful, and if ordinary care is exercised there is little risk attending the transplanting. It will, of course, be evident that this kind of hedge is employed for gardens and pleasure grounds, not for field purposes. The present time and season are especially suitable for planting this and kindred varieties.—C. E. CURTIS (in "Estates' Gazette.")

— **EXPORT OF INDIARUBBER FROM THE AMAZON REGION**.—The latest report of Mr. Churchill, the British Consul at Para, which is the chief port to which the shipping of the Amazon resorts, shows that the greater part of the great rubber production of the Amazon region is exported from Para. In 1896 the value of this export from Para was nearly three and one-half million sterling, of which Great Britain took over one and three-fourths million, nearly the whole of the remainder going to the United States. The quantity was 15,226 tons, the total export from the Amazon being 10,981 tons, the balance being shipped largely at Manaus, about one thousand miles up the river. The chief sources of production, says "The Times," are along the great rivers and islands in the Amazon belonging to the State of Para, the valleys of the main tributaries of the Amazon, such as the Parus and Madeira, and the Amazon districts of Bolivia and Peru. Mr. Churchill gives a long account of this remarkable industry in the Amazon region, its history, the mode in which it is now carried on, the profits, the varieties of the gum, and the like. The most important observation he makes under this head is that the supply is regarded by competent authorities as inexhaustible, because the tree is being continually reproduced by Nature. Some areas, such as Cameta, on the Tocantins, have become exhausted, but when abandoned for a time they recover, and many districts have not been tapped at all. The area producing para rubber amounts to a million square miles, and further exploration will probably show that this is under-estimated. The richest zones at present known are along the banks of the southern tributaries of the Amazon, and on the islands in the main stream. Some of the northern tributaries have not been explored. Cocoa and Brazil nuts are the chief exports after rubber, but they are of small importance compared to it; and although the region produced rice of excellent quality it is no longer cultivated, as all the labour is absorbed in the rubber industry, and the people live almost wholly on imported food.

— **LAYING TURF.**—The moist, mild weather prevailing affords an excellent opportunity for repairing bad places on lawns with new turf, or even for laying down a new one. Where hollow places exist the turf may be raised and fresh soil added, so as to bring it up to the surrounding level. Make firm and replace the turf, beating it down level.—E.

— **DECEMBER WEATHER AT DOWLAIS, GLAMORGAN.**—Rainfall 8.76 inches, which fell on twenty-five days; greatest fall 2.82 inches on the 26th. Temperature: Mean maximum, 44.226°; mean minimum, 34.807°. Highest reading, 55° on the 3rd; lowest, 23° on the 19th. Below freezing point on thirteen occasions. There were twenty sunless days. The wind was in the S.W. and W. on twenty-three days. A very dirty month throughout. The first nineteen days were wet with the exception of the 13th, then fine until the 25th. In the last eleven days 4.90 inches of rain was registered. Total rainfall for the year, 46.95 inches, which fell on 199 days, frost on 105 days. Total sunshine, 1135½ hours; sunless days, 143.—WM. MABBOTT.

— **HEAVY RAINFALL.**—Though we cannot afford space for ordinary tabulated forms of rainfall, we make an exception in this case as it exceeds 40 inches. Mr. Thomas Singleton, in sending the monthly amounts from The Gardens, Curraghmore, Co. Waterford, observes that when reading accounts by gardeners of the dry season of 1898 he has often felt he should "like to spare them some rain," as he has had "too much." Here follows his record of the monthly rainfall, 1898:—January, 4.37 inches; February, 1.59; March, 0.54; April, 5.17; May, 2.77; June, 3.49; July, 1.08; August, 4.23; September, 3.77; October, 7.23; November, 3.06; December, 4.75—42.59 inches. It will be observed that October was a very wet month, while January, April, August, and December were not parchingly dry.

— **METEOROLOGICAL RECORDS IN THE ISLE OF WIGHT.**—During the year 1898 at Newport there were 150 wet days, the total rainfall being 28.24 inches. The maximum temperature for the year was 85.8°, on the 15th of August; the minimum 24.6°, on the 22nd of March. The wettest day in the year was the 23rd of November, when 1.76 inch of rain fell. The average rainfall for the last twelve years is 29.57 inches. At Totland Bay, which is thirteen miles west of Newport, there were 137 wet days, and the rainfall was 25.60 inches. The hottest day was recorded on September 7th, when the thermometer registered 80.5° F.; the warmest night September 17th, 64.2° F. The coldest day February 22nd, 38.2° F.; and the coldest night November 23rd, 29.6° F. The wettest day was on February 21st, when 1.36 inch of rain fell.

— **DECEMBER WEATHER AT BELVOIR CASTLE.**—This month was very changeable, with almost double the average amount of sunshine, and was much warmer than November. The wind was in a southerly direction twenty-five days. The total rainfall was 1.99 inch, which fell on fourteen days, and is 0.09 inch below the average for the month. The greatest daily fall was 0.40 inch on the 8th. Barometer: Highest reading, 30.467 inches on the 21st at 9 P.M.; lowest, 29.129 inches on the 29th at 9 P.M. Thermometers: Highest in the sun, 58° on the 5th; lowest, 21° on the 31st. Mean of daily maxima, 49.67°; mean of daily minima, 38.48°. Mean temperature of the month, 44.07°. Lowest on the grass, 17° on the 31st; highest in the sun, 87° on the 18th. Mean temperature of the earth at 3 feet, 44.80°. Total sunshine, 63 hours 50 minutes. There were ten sunless days.—W. H. DIVERS.

— **A BALMY JANUARY SUNDAY.**—A finer day than last Sunday has rarely been experienced in London. As a daily paper remarked, it seemed to take us once more right out of the winter season. The sun shone with great power nearly all day, and even in the shade the thermometer rose to a maximum of 56°. This was as many as 13° above the average for the time of year, and was within a degree of the normal maximum temperature for the month of April. So high a January reading had not been registered in London since 1890, and in the course of the past fifty years there were only two warmer days, the highest point reached being in 1876, when the thermometer on the 31st rose to 58°. So far as we have gone, the present month seems to have been scarcely so mild as last January, but there has been in the southern part of the country nothing like genuine wintry weather, and with the existing state of atmospheric pressure there is no immediate prospect of such a change. The past few days have been remarkable for the persistence with which cyclonic disturbances have advanced from the Atlantic and passed northwards along our western and northern coasts. Owing to these movements the air has not only been mild, but highly charged with moisture, so that in the intervals of fine weather, the ground has remained extremely wet and muddy.

— **DEVON GARDENERS' ASSOCIATION, Spring Programme.**—January 18th, Mr. R. W. Hodder, "The Fungi Pests of our Gardens, with Notes on Rust in Chrysanthemums;" February 1st, Mr. J. Mayne, "Liliums and Their Treatment;" February 15th, Mr. E. J. Love, "The History of the Rose;" March 1st, Mr. G. Camp, "Plants for House Decoration;" March 15th, Mr. J. Stiles, "Chrysanthemums: Their Culture, with Hints on Dressing, Staging, and Judging the Blooms;" March 29th, Mr. G. C. Crabbe, "Pelargoniums: Their Treatment from an Amateur's Standpoint."—A. HOPE, 54, High Street, Exeter.

— **FRUIT CULTURE IN ASSAM.**—The experimental cultivation of fruit trees in Assam does not seem to have been attended with any degree of success, judging from the results recorded in the report of the local Agricultural Department for last year. It seems that six grafts of each of six varieties of fruit trees (it is not stated what the varieties were) were supplied during the year for experimental cultivation at Kohima and the Sanitarium ground at Nemotha, in the Cachar district. Some of these were planted in a cemetery! Others in the Lunatic Asylum grounds at Tezpur. Many of the imported plants have since died, but we do not feel any surprise. This simply goes to show that Assam is in need of a properly organised Botanical Garden, Agri-Horticultural Society, or Government Experimental Farm, where trials of indigenous and exotic plants of economic value could be conducted on a systematic basis. Experiments conducted on the promiscuous and haphazard system, noticed above, are not only quite valueless, but a waste of public funds and official energy. Assam abounds in planters who are keenly interested in all matters relating to the cultivation of plants of economic value, and we have little doubt that they would not only support liberally a local Agri-Horticultural Society, but would furnish valuable information to the Society and the local Agricultural Department.—("Indian Gardening.")

FRUIT ON DWELLING HOUSES.

FOR many years I have felt regret at the waste of wall space on buildings, and a "deal" in Pears from a wall this season has only added strength to my previous convictions. Pitmaston Duchess at 2s. per dozen wholesale may not seem a very high price, but with good crops, ten or twelve trees, similar to those from which the fruits referred to were gathered, would have yielded £15, and I have no hesitation in saying that had I been fortunate enough to have held a ton of such Pears, they could have been disposed of at as good or better prices.

Apart from the commercial aspect of the question, however, there is the domestic side—the growth and use of fruit for the home. In thinking over the subject one is inclined to speculate as to how many superficial acres of wall space in this country are covered with the beautiful forms of Ampelopsis, Ivies, Cotoneasters, Roses, and the many other charming climbers, that render the outsides of so many homes so very beautiful. Owners of large establishments who have walled kitchen gardens are quite justified in covering their abodes with creepers, and it is not for me to grumble. But to the dwellers in villas and cottages this does not apply, and to them some of our best Pears would, no doubt, be more than acceptable; and why not Plums, and in many cases Apples? On an eastern aspect Plums grow and produce good crops of fruit in gardens, and it is reasonable to suppose they would thrive equally well on dwellings. The same applies to Pears on a wall facing west. For any but the most enthusiastic of amateurs with ample spare time I would not recommend Peaches, but in many cases the back offices of premises facing north might be made to produce good crops of Morello Cherries.

With the facilities for learning now within the reach of all there should be no difficulty in mastering the art of pruning and training, but in a case of doubt there is usually some local gardener who will be ready to help, and to show as far as possible what is best to be done. In these go-ahead times what is the cost of a fruit tree? while the necessary attention after planting would scarcely mean more than a few hours in the course of a year. Place these items on one side of the ledger and the returns on the other, and who would not enjoy the delicacy of Doyenné du Comice, or the lusciousness of Marie Louise, or the grand proportions of Pitmaston Duchess Pears of his own production? This is saying nothing of the other useful fruits to be had in Plums and Apples. If either of these was in request then are there plenty from which to choose. I might venture to say this would be a method, if only in a very small way, of stopping some of the tremendous importation of foreign fruit, and the consequent outpouring of cash that might well stay at home.

There are difficulties to contend with, no doubt: dwellings are too near each other, and light is blocked, hard paths run close to the walls. The landlord might say, "I am not going to plant fruit on my houses." The tenant decides that as he may not stay long he will not work for the benefit of the incomer, and so on *ad infinitum*. But think of the Jasmine on the walls of houses with its silvery showers of fragrance, of the Roses that bloom so long and so sweetly: and again, of the Ivy covering the rude building materials with the glossy sheen of its leaves. Who planted these? Somebody, surely, and in doing so could not have thought of themselves alone, but of those who were to follow them in the years to come. Are they not appreciated, and would not fruit be equally as highly thought of?—J. SHALFORD.

LUTON HOO PARK.

THIS, the princely estate of Madame de Falbe, is situated a little over two miles from the busy town of Luton, the entrance from which is under an archway, with lodges on each side. Directly within the park the ground begins to rise towards the mansion, to which access is gained by a long drive through the park, which is well furnished with splendid timber trees. To the left is a large lake, about a mile and half long and nearly half a mile in breadth, well stocked with various waterfowl. Near the mansion is the entrance to the pleasure grounds, which extend to nearly 100 acres, and there are miles of well-kept gravel walks and acres of lawn. The illustration (fig. 7) gives a view of the mansion with trees in the foreground.

The grounds are beautifully undulated, and contain many features of interest. Trees, plants, and shrubs of every description have been planted with admirable discretion, while there are dells, ravines, roseries in various parts of the ground, and in a secluded spot is a graveyard devoted to canine pets. Gigantic trees, such as *Picea macrocarpa*, Cedars, *Picea pinsapo*, *Picea glauca*, *Thuia gigantea*, the Douglas Fir, *Araucaria imbricata* are only a few of the many that are conspicuous, many being from 40 to 50 feet high adorn the estate, as do grand Portugal Laurels, *Arbutus*, *Laurustinus*, and Weeping Hollies, 15 feet high, 15 through, sweeping the ground. An enormous Beech tree, 29 feet in circumference round the trunk, is well worth mentioning.

Clumps of *Kalmias*, *Rhododendrons*, with Lilacs and Laburnums, occupy a suitable position in the American garden, while the dell of hardy Ferns forms a most pleasing feature. In various situations in these extensive grounds one comes in contact suddenly and unexpectedly with plots devoted to diverse styles of gardening. For instance, there are two or three Rose gardens, herbaceous borders planted with the very best varieties of their respective sorts, one Rose garden devoted to the *Rugosa* varieties, in which the bright berries are very effective this dull season. Another is devoted to Hybrid Perpetuals, a third to Teas, and so on. Many good flowers could have been cut on the day of my visit during the first week in November.

Splendid specimen *Andromedas* attract one's attention, as do beds of *Acer Negundo variegata*, with *Tropæolum speciosum* climbing up their stems. *Iris Kœmpferi* in variety makes a novel and showy bed, and close by these in a quiet nook is an aviary of doves, who are allowed the liberty of going where they please. As one nears the stately mansion the borders of the principal walk are planted with a choice collection of herbaceous plants, annuals, &c., of which many were still in flower. Large beds are full of *Aquilegias*, dotted with various *Liliums*, *Tritomas*, and *Nicotianas*. Dahlias, too, find a place with *Antirrhinums*, *Pentstemons*, and scores of others. Over a portion of a trellised archway Crimson Rambler Rose wanders vigorously, and is most handsome.

MEMORIAL TREES.

The number of memorial trees that have from time to time been planted by royalty and other distinguished visitors is very large, and these alone make the demesne additionally interesting to visitors. Their variety and age may be gathered from the subjoined tabulated list:—

<i>Fagus purpurea</i>	... planted	Dec. 1878	H.R.H. Prince of Wales
<i>Quercus coccinea macrophylla</i>	Dec. 1879	H.R.H. Princess Christian	
<i>Quercus pannonica</i>	... Oct. 1880	Julia Countess of Jersey	
<i>Abies Clanbrilliana</i>	... Nov. 1880	The Honble. Jane Macdonald	
<i>Picea magnifica</i>	... Nov. 1882	Lady Berthwick	
<i>Wellingtonia gigantea</i>	... "	Lord Dorchester	
<i>Quercus pannonica</i>	... "	The Honble. J. J. Bourke	
<i>Abies excelsis aurea</i>	... Dec. 1882	Countess of Gosford	
" <i>Inglemani</i>	... "	Honble. F. Capel	
<i>Cupressus erecta viridis</i>	... "	Lady Rosamond Fellows	
<i>Picea concolor</i>	... "	Lord Dupplin	
<i>Abies Menziesii glauca</i>	... "	Lady Muriel Hay	
<i>Thuia gigantea</i>	... "	Honble. Sybel Capel	
<i>Pinus excelsa</i>	... Nov. 1883	Mons. de Falbe	
<i>Picea Pinsapo</i>	... "	Miss Claughton	
<i>Abies Finedonensis</i>	... "	Bishop of St. Albans	
<i>Picea magnifica</i>	... "	Lady Virginia Sanders	
<i>Picea nobilis</i>	... Aug. 1884	H.S.H. Prince Edward Saxe-Weimar	
<i>Cupressus Lawsoniana</i>	... "	H.S.H. Prince Edward Saxe-Weimar	
Purple Beech	... Dec. 1884	Madame de Staal	
Scarlet Beech	... "	Mons. de Staal	
Green Beech	... "	Comte Piper	
<i>Cedrus deodara</i>	... Dec. 1886	Comte de St. Priest	
<i>Abies Nordmanniana</i>	... "	Princess of Wales	
"	... "	Maria Marchioness of Aylesbury	
"	... "	Colonel Montague	
<i>Araucaria imbricata</i>	... "	Lady Emily Kingscote	
<i>Cedrus deodara</i>	... "	Marchioness of Ormonde	
<i>Wellingtonia gigantea</i>	... "	Prince John of Clutzberg	

TERRACES AND FLOWER GARDENS.

The terraces and flower gardens adjacent to the mansion are very extensive, and there are some superb specimen Bay trees 18 feet high, and as much through, in tubs here and there, that have a grand effect. The flower garden contains very large beds of a suitable design for the situation. In the centre is a grand fountain, and to give one an idea of the extent of this garden it may be stated that 80,000 bedding plants are used annually. Another year I hope to describe in detail this garden, as it is both novel and interesting when in perfection.

The panorama from the terrace is of singular beauty, as a large extent of country can be seen, with grand belts of trees beyond, which in full autumn glory were beautiful in the extreme. Then the noble trees in the park, the green sward, with fine herds of cattle, and the waterfowl on the lake, made a picture worthy a long journey to see. On the side of the mansion, in which is the main entrance, is a circular drive with an expansive lawn, with a central equestrian statue. I must not forget to mention some splendid clumps of Bamboos, which have been out some few years, and are very attractive.

THE GLASS DEPARTMENT.

The glass is very extensive. The first range is a long lean-to in several divisions. The late vinery containing Black Alicante, Gros Maroc, and Lady Downe's is full of vigour. The Vines were planted in February, 1897, and have given splendid results. In the Muscat of Alexandria house there has been a grand crop, while plants of Tangierine Oranges and 'pot Figs occupy the space under the Vines. Then comes a show house, 60 feet by 21, with Camellias planted on the back wall. The stages are occupied with well grown and profusely flowered *Bouvardias*, *Salvias*, *Cannas*, *Pelargoniums*, and *Marguerite*, a grand *Bignonia venusta* covering the roof. In the Palm house *Kentias* and *Cycads* are conspicuous, with *Cibotiums*, *Alsophilas*, *Adiantums*, and one of the largest specimen *Platyceriums* I have seen. The early vinery contains Black Hamburg, of which bunches are usually ready for the table in May, and preparations are already advanced for the next crop. The same variety is the favourite in the second early vinery.

The plant houses are of equal importance. A three-quarter span structure 48 feet by 24 is used as a store, the centre of which contains specimen Palms, some noble Bananas, which fruit freely, *Dracænas*, *Crotons*, *Anthuriums*, with flowering plants on the stages. In the cooler section trained *Azaleas*, occupy the centre, smaller plants the side, while grand plants of *Lapagerias rosea* and *alba* on the roof are very noticeable. A Peach and Fig house is used to advance *Chrysanthemums* to keep the show house gay. Of great value to Mr. Maycock are several plant houses, in which are 500 tree Carnations in 48-pots, dozens of well grown *Calanthes* producing enormous spikes, and *Cypripedium insigne* full of flower and bud. These two Orchids as seen here would be hard to beat for winter flowers. *Clerodendron fallax* flowering freely is a distinct attraction, and as an autumn decorative plant should be more extensively grown. *Malmaison* Carnations, of which there is a grand collection, will undoubtedly produce some handsome flowers. I noticed in these houses standards on 4 feet stems, with good heads, *Aloysia citriodora*, which is a great favourite with Madame de Falbe. There are a dozen or more of these, and they are certainly novel.

The Rose house is 50 feet long, 30 feet wide, and proportionate in height. In it was a show of *Chrysanthemums* worth going a long way to see. The plants were arranged in banks all round, and comprised all the best varieties in cultivation. Many of the blooms would have done justice and credit upon the exhibition boards. In another house the stages were about 500 plants of *Chrysanthemum Segur Melaine* in 48-pots, well flowered, intermixed with about 200 of the scarlet *Salvia splendens*. It was a novel and striking combination. A shelf over the path was devoted to *Cyclamens*. The plants were in excellent condition, and will shortly be in perfection. *Begonia Gloire de Lorraine* in 48-pots, nearly 3 feet high, 2 through, from top to bottom one mass of flower, mixed with Palms and pots of Roman Hyacinths, stage-draped Ferns, and *Ophiopogons* made an attractive display. Well-coloured *Dracænas*, *Crotons*, *Aralias*, and other plants suitable for table decoration are largely grown, as are *Stephanotis* and *Gardenias*. Another range is wholly devoted to Melon, Cucumber, Tomato growing, and the plants are still producing grand fruits. In the Tomato division some *Marguerite* Carnations, lifted from the open ground and potted, are flowering freely.

THE FRAME GROUND.

The frame ground is an important department, in which alone are Carnations of the best sorts to the number of about 18,000 young plants. Violets total up to over 3000 plants in the frames. Marie Louise, Prince of Wales, J. J. Astor, and Comte de Paris are the prime favourites. Mushrooms are grown extensively, and a finer crop would be impossible to find. The outdoor bank or ridge system is adopted, and they were literally covered with fleshy Mushrooms. Cuthbert's spawn was used.

The kitchen garden occupies 6 acres, and it was planted with fruit trees. A Peach wall 100 yards long produces grand fruit. Strawberries are grown in pots by the thousand, and for forcing Royal Sovereign, President, Vicomtesse Hericart de Thury, and Sir J. Paxton are the favourites. Vegetable supplies are an important factor on an estate like this, the house demand being very great, but from what I saw of the crops, and the utilisation of the ground, nothing is lost, grand successive crops being the order of the day.

Behind one of the long ranges are the garden offices, bothies, stoke-holes, and fruit room. These are well arranged, and the comfort of the young men is well studied, the rooms for the outside men being also very convenient. The fruit room is of good size and well arranged, and the contents at the present time comprise mainly Apples and Pears. Another good feature of this establishment is the gardener's house, conveniently situated near the offices. It is a solid, square-built erection, possessing superior accommodation, and is occupied by Mr. G. H. Maycock, the gardener in chief, who has held this important position for some years with satisfaction to his employer and great credit to himself, for none but a thorough practical all round man of great experience could manage such a place of importance as Luton Hoo.—A. OUTRAM.

PRUNING AND CLEANING VINES.

AFTER the leaves have all fallen from the Vines and all the Grapes have been cut, there is nothing to prevent the important operations of pruning and cleansing being carried out. This work is best dealt with as soon as possible during the present month, or earlier if convenient. Vines enjoy a rest, which they can indulge in if the superfluous growths are cut away promptly and all the cleaning disposed of, followed by cool treatment with free ventilation.

Pruning Vines requires intelligent care and good judgment. If the Vines are old and have formed spurs on each side a main rod, the orthodox method of pruning consists in shortening the lateral growths to one or two buds. Pruning so as to leave more buds may result in securing finer bunches, but it has the disadvantage of causing long spurs to be originated, which eventually prove inconvenient. Smaller and compact bunches usually appear from the lower buds, one of which only should be allowed to fruit. The other, if retained nearer

plan is to take a less bold, but still effectual, plan of renovation. Allow a strong growth to extend from the base originating in a suitable position. When it has grown beyond 6 feet, if strong, stop it at that length, allowing a fresh leader to grow as much as it likes during the season. If growths break out from the eyes at the base of the principal leaves on the length below the point of stopping, shorten them to the first leaf they make, continuing to do the same if subsequent growth is made. Give the new cane every opportunity to become well ripened.

The following season, after the winter pruning, only the first 4 feet of cane is retained, the rest being pruned away. The spurs on the old rod may also be removed as far as the new cane extends, because it will be necessary to have room and light for the future growth of laterals. From the upper bud of the new cane a leader may again extend, to be stopped at 4 feet, or less if vigour of growth does not warrant so much. A fresh leader can be allowed to grow at will as before, until pruning time in winter, when it is shortened back.

FIG. 7.—LUTON HOO PARK.

to the old rod than the fruiting shoot, must be kept as the lateral for pruning back the following year, thus preventing undue extension or elongation of the spur. Frequently the risk must be run of shortening the spur back into the old wood, when it is imperative to remedy unsightly elongation and trust to the starting of a dormant bud to form a suitable shoot. Such buds do sometimes extend growths without prior shortening of spurs, and it is desirable to encourage them when the reduction of long spurs calls for attention.

To make the best of these shoots and render them useful for the purpose they are intended for, they must be given sufficient room to extend in light and air, so that large principal leaves are formed which will build up good basal buds for subsequent pruning to. Stop them at the seventh leaf, and the sub-laterals to one leaf, and rub out weaker growths from the old wood competing with them.

Old Vines may be improved by dispensing altogether with ancient rods, especially when knotted and gnarled spurs so prevent a free flow of sap that only weak annual growths are produced. To cut the old rods boldly down is a desperate remedy, and will certainly result in no crop, but strong growths start and in time prove fruitful. The usual

Remove spurs as before. The same course may be pursued annually until a new rod has been fully built up, and the old one can be removed. All young canes must be kept in a depressed position, or the lower buds will not break well.

The cleansing of the rods must follow pruning, using some approved insecticide or softsoap, 4 ozs. to the gallon of water, in which a little sulphur is dissolved. Work the mixture well into every crevice. The barbarous method of peeling off bark should be avoided, but any very loose portions may be removed.

The woodwork and glass of the house ought to be effectually cleansed, but when the paint is in bad condition, a fresh coating should be given, white always being preferable for the interior of glass houses. Limewashing the walls is a process which must not be omitted, using newly slaked lime.

Dry borders must be moistened with water or liquid manure, and the surface of borders renewed with an inch or two of fresh compost. Free ventilation in favourable weather should be given to all ordinary vineries until March, when they may be kept closer and the Vines encouraged to break freely.—E. D. S.

ISLE OF WIGHT CHRYSANTHEMUM SOCIETY.

THE annual meeting of this Society was held at Newport on Saturday last. Dr. J. Groves, B.A., J.P., presided. The report and balance-sheet were adopted on the proposition of the Chairman. The balance in hand is £4 13s. 9d., which is satisfactory, considering the inclemency of the weather at last year's show. Sir Chas. Seely, Bart., was re-elected President, Dr. Groves Chairman, and Mr. C. H. Cave Hon. Sec. Several alterations were made in the schedule for improving the standard of excellence, giving variation and effect to the exhibition, and placing the Society in a better financial position. In the discussion suggestions were made by many old exhibitors and enthusiastic horticulturists, which will, no doubt, receive due consideration.

CHRYSANTHEMUM TRADERS.

UNDER the above heading, "A. D." seems (on page 13) as much "at sea" as the writers of those catalogue notes to which he refers. He asks, Is it trade bluff? I can only enlighten him upon one point—i.e., the N.C.S. is the cause of it all. He also asks, What do the public care about such trivial things? I think the public like to know facts, and so long as the N.C.S. give their gold medals to other things besides Chrysanthemums, and grown by nobody knows who, so long will the catalogue war go on. This is not the first or second year of splashes for effect and all the rest of it, and I do not think a continuance of the present system can be conducive to the permanent welfare of the Society. Does "A. D." think it can?—W. WELLS, *Earlswood*.

N.C.S. PRIZES.

THERE is at least a note of freshness in the literary combatant "A. D.'s" communication on page 13 last week. One would have thought he would have been among the last men to object to a little pen sparring in catalogues or elsewhere; but when he sees things that do not please him might he not ask himself—"Is there not a cause?" Can he answer a few questions on a subject that is not quite trivial to a considerable number of Chrysanthemum growers and supporters of the N.C.S.?

Was not the National Chrysanthemum Society established to increase the interest in and promote the superior culture of the Chrysanthemum? Have the whole of the funds provided by members—many of them hard working, genuine cultivators with little money to spare—been devoted in the form of prizes to real and actual cultivators of the products to which prizes have been adjudged? Is it reasonable and right that a special society, established for a special purpose, should go beyond what may be described as its charter, and spend the money subscribed in the form of medals for exhibits very different from Chrysanthemums, and granted to persons who never grew what they exhibited in the form of various plants, or other things which have been brought together for winning them?

Does any other special society in the world go beyond the object for which it was formed to the same extent as this? Do the National Rose, Carnation, Dahlia, or any other society take such flights outside their legitimate sphere as the N.C.S.? Does the grand autumn flower, with its commanding beauty, need crutches to enable it to hold up its head? Ought not it to be the last to need such props as are provided by the generosity of those to whom its resources are entrusted?

Blame not exhibitors who win the honours placed within their reach. Men of enterprise naturally take advantage of the opportunities afforded; and if they did not their negligence would not speak much for their business capacity. They are justified in winning medals when they can within the stipulations. But what of the policy of a great society that goes so far beyond its own special functions as to dangle prizes for products which do not, and in their very nature cannot, represent the cultural skill of the exhibitors who win them? Let "A. D." look at the matter from a rather broader point of view, and give his unbiased opinion on the points suggested, and any others that he thinks cognate to the policy of the N.C.S. He may then, perhaps, find a cause for catalogue splutterings.—A MEMBER, BUT NO TRADER.

BULBS.—As soon as bulbs placed under the plunging material have commenced growth and advanced an inch or two the pots should be removed and placed close to the glass in a frame. Shade at first, but gradually inure to the light. The green colour does not readily develop in the coldest weather.—S.

COMPOST FOR PEACH BORDERS.

YOUR genial and intelligent correspondent, "A. D.," asks (page 494, last vol.) for criticisms on this important subject. Like himself, I do not approve of the "recipe" he quotes. Throughout a long practice, and having had to do with a considerable variety of soils and climates (for I venture to say climate should be taken into account in this matter), I long since arrived at a dislike for elaborate mixtures for fruits and most other plants. My conviction and experience lead me to recommend what I shall term a simple maiden staple, with comparatively little else added to it, and giving especially animal droppings a wide berth.

In reference to Peaches, and, I may say, all stone fruits, I take it to be an established fact that they can be more certainly and easily grown to the greatest perfection in a rather strong calcareous loam resting on a well drained bottom. I believe I am correct in saying the limestone districts in this country produce the finest Peach trees, all other things being equal.

To produce the healthiest, longest lived, and most fruitful Peaches I would recommend, when it can be had, 6 inches, or not more than that depth unless the soil be exceptionally good, and of course including the verdure, from old calcareous grass land. This, stacked for six or nine months, and then having 2 cwt. of half-inch bones, 1 cwt. of bonemeal, one cartload of old mortar, and one load of pounded charcoal well mixed with twelve loads of the loam, will make a first-rate Peach border. If I used any quickly soluble manure it would be a very small quantity. It is presumed that the trees to be planted are young, and, as all very well know, such are apt to grow too strongly. Such a border will be more fruitful to begin with, and one that will form a sound healthy medium for being mulched and fed with more soluble manures when such become necessary.

I have referred to long-lived Peach trees. It may be interesting to relate that in 1858 I took charge of a Peach house in which there was a tree which, at that time, appeared to me to be about twenty years old. For the ten years I had charge of it I forced it to ripen its crops in April and May without my ever having done anything to the border except applying top-dressings. I had the pleasure to see this tree standing in the same place last summer, and was delighted to see my old friend still doing duty. This speaks much for its border, and perhaps more for the management of my successors. The variety is *Violette Hâtive*, a Peach yet hard to beat in many ways. I may say the natural soil of the garden is a splendid loam, and the climate bright and dry as any in Britain.

I should be sorry to convey the idea by these remarks that very considerable success in Peach culture is not attainable except when fine calcareous loam from an old pasture can be had. I have, no doubt like "A. D." and many of your readers, seen fine Peaches grown in ordinary good kitchen garden soil resting on a dry bottom, and not deeper than 18 or 20 inches, and your readers who cannot procure such soil as is considered the best should not be discouraged.—D. THOMSON.

In your issue of December 29th, 1898, your able correspondent, "A. D.," invites criticisms on making a Peach border. The recipe for the compost then given I consider too rich, and would consequently cause the trees to make long-jointed unfruitful growth. If about to make a Peach border I should prefer ten loads of good sound turfy loam, a little adhesive in texture, four loads of light garden soil, two loads of old mortar rubbish, and one sack of charcoal, broken about 2 inches long, all well mixed of the quantities required.

If the site were cold and the subsoil wet I should make the border a foot above the level of the ground, concreting the bottom, and adding 4 to 6 inches of drainage after the concrete was set, then cover the drainage with turf, grass downwards, or any coarse lasting material. If the subsoil were dry I should make the border level, 2 feet 6 inches deep, well firming the bottom, and place a layer of brick rubbish for drainage and cover it with turf or rough material. After the border was made and the trees planted and watered, mulch with long litter with the manure shaken out. When the trees were established I should feed from the surface by mulching, or with liquid manure, instead of giving a rich soil to begin with. I have proved this to be a very safe plan and successful.—T. T.

THE opinion of practical Peach growers is asked as to the suitability of the recipe given on page 494, last vol. The ingredients are ten loads of turfy loam, and six ditto of manure in various forms. I have no hesitation in condemning this mixture entirely. The fresh horse droppings and other additions to the turfy loam are quite unnecessary; in fact it would cause positive injury to any unfortunate Peach trees that might be planted in it. The trees would doubtless grow at a rapid rate, but before many months had elapsed that scourge of Peach growers, gumming, would be observed on many of the branches, and if several growers had made their borders according to

the above recipe, our editor would be inundated with inquiries for the cure of the evil.

A very little practical experience is worth a great amount of theory, and as Peach culture has been rather extensively carried out in the gardens of which I have charge, I will briefly state the simple ingredients we use. At the present time we have upwards of sixty trees planted under glass. Our soil is heavy on the magnesian limestone formation, too heavy for Peaches; we therefore use loam of a lighter texture, somewhat inclined to be sandy, in the proportion of one-half. To ten loads of the above we use about three barrowloads of wood ashes, and the same quantity of broken brickbats about the size of a pullet's egg. No manure of any description is used. The border is well drained with rubble, and a drain is laid in a convenient place to carry away the surplus water. The border is not made more than 18 inches in depth. The soil is made very firm and the trees planted. We formed a border on the above lines in the autumn of 1890. The trees were obtained from a well known nursery whilst they were in green leaf, as the house was intended for early forcing. They made rapid growth the first season, and during the past summer a heavy crop of large handsome fruit was gathered before the end of June. The majority of the trees were 12 feet in height, and, where they had room to develop, were as much through. The trees were and are now in the best of health.

All that is required to grow good Peaches is sound loam of medium texture. If the soil is deficient in lime some lime rubble may be added with advantage, but care is required in selecting, as the lime made from the magnesian limestone will often do more harm than good. Hence the reason we prefer broken brickbats where lime is not necessary.

If good Peaches can be grown and the trees kept in a healthy condition on the above simple lines, why use an expensive and unsafe concoction as mentioned in the recipe cited?—S., *Yorks.*

In response to the invitation of "A. D." for expressions of views, my experience leads me to think that the rich fare so often provided for Peach and Vine borders is not essential to the production of fruit either in quantity or quality. If the turfy loam and various manures were used less freely in the making of borders, more opening material being added, the borders would be in a condition to sustain healthy root action after the first few years. That turf freely used does induce rapid growth there is no doubt, as the roots, by the fermentation of the fibre, are in a mild hotbed; but after decomposition has taken place the soil settles into a cold mass through which water and air cannot pass freely.

For the past seven years I have had the management of three Peach houses. The trees have borne heavy crops of fruit each season, improving in health at the same time. They have all been lifted, but no fresh soil was used. The soil from one side of each tree was carefully picked from among the roots and burnt refuse freely mixed with it as hot as it could be obtained from the fire heap, as well as a few barrowloads of mortar rubbish. These were well mixed, and the following day the mixture was dry enough to bear ramming without running together. The drainage having been seen to, we commenced to fill in the border. As the soil was returned it was trodden and rammed as firmly as possible. When within 6 inches of the original border we commenced to lay in some of the roots, covering them with soil and treading it firmly; the surface was then mulched with short litter and a watering given. In May the whole of the borders were mulched with short litter. The trees were watered with weak liquid manure each time water was necessary.

Towards the end of the year the mulch was raked off, and a good dusting of lime pointed in. Later the houses had a dressing of earth-closet manure, watered in with stronger liquid manure. The borders are 18 inches deep, with from 3 to 6 inches of drainage. As the prunings of shrubs, trees, and old Pea stakes were used in burning the refuse, and these kept covered over to smoulder, the heap contained charcoal and wood ashes.

Chrysanthemums, Arums, Azaleas, and other pots were stood on the Peach and Vine borders; but the watering of these did not prevent the roots working on the surface, which we attributed to the firmness and porosity of the borders.—S. BACKHOUSE, *Shrewsbury.*

THE VALUE OF LIME.—It is well known that lime is a valuable agent in correcting the sourness of land, in unlocking the unavailable potash, phosphoric acid, and nitrogen in the soil, and as a general soil improver. Many plants are benefited by the application of lime to the soil, but some are injured by it. Experiments made at the Rhode Island Experiment Station show that Onion, Parsnip, Celery, Cauliflower, Spinach, Lettuce, Beet, Asparagus, Cucumber, Cabbage, Turnip, Peas, and Kohl Rabi are benefited by its use; that Carrots, Potatoes, and Rye are indifferent to liming; Sorrel and blue Lupines are positively injured by the use of lime. Lime is especially valuable to land that has been continually heavily dressed with stable manure, and which is showing signs of being less fertile than formerly.

SIR W. T. THISELTON DYER, K.C.M.G.

THE distinguished and popular director of the Royal Gardens, Kew, will be the recipient of a host of congratulations, in which we cordially join, on the occasion of the honour of knighthood conferred upon him in recognition of his services to Colonial Governments.

When Sir William, then Mr. Dyer, was appointed to his present position in 1885 we published his portrait and gave a sketch of his career, and said of him:—His devotion to science, and especially natural science, his notable antecedents, and his ten years' probationary work as assistant director of the Gardens, eminently fitted and recommended him for the appointment. The directorship of Kew is a post that requires of the holder a special training. It is one which no mere botanist, any more than no mere gardener, is capable of filling satisfactorily, but it requires a judicious combination of the two. These qualities are well met in Mr. Dyer, who, though eminently a man of science, has also a broad practical side which can be turned at any time in the direction where it is required. He knows that science without practice is dead, and that it is only when applied that it is really living.

Mr. Dyer was born on July 28th, 1843, in Westminster, and his early education was acquired at King's College School, and he entered the medical department in 1861 as Warneford scholar. In 1863 a junior studentship at Christ Church, Oxford, was offered for open competition, which he had the good fortune to obtain. His first appointment was that of Professor of Natural History in the Agricultural College of Cirencester. In 1870 Mr. Dyer became Professor of Botany in the Royal College of Science for Ireland in succession to Dr. Wyville Thomson. Part of his official duties in Dublin was to deliver a short course of popular lectures. Reports of these appeared in some of the Irish papers, and were reprinted in the "Gardeners' Chronicle." This circumstance brought him to the notice of the Royal Horticultural Society, from whom he received an invitation to join the staff as Professor of Botany with a seat on the Chiswick Board of Direction, and he returned to London in 1871. In 1875 the Government revived the office of Assistant Director of the Royal Gardens, and Mr. Dyer was offered the appointment. Having taken up his residence at Kew two years previously he had opportunities of becoming acquainted with the work of the establishment, and he accepted the offer, though with some misgivings, as it seemed to close the door finally to a teaching career, which he had then most at heart.

Mr. Dyer ("as was") is a Fellow of the Royal Society, and in consideration of his admirable management of Kew, and of services rendered to the Crown Colonies, her Majesty conferred upon him the distinction of Knight Commander of the Most Distinguished Order of St. Michael and St. George. May he long live to enjoy the well-merited recognition, which is a compliment also to botany and horticulture.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—JANUARY 10TH.

AS is customary at the opening meeting of the year exhibits were by no means numerous. They were, however, fairly well diversified, and contained several plants of more than average interest. Orchids were good, as were the fruits from Mr. W. J. Empson.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with the Rev. W. Wilks and Messrs. G. Bunyard, J. Cheal, J. H. Veitch, W. Poupert, J. Gleeson, A. H. Pearson, A. Dean, A. F. Barron, W. Bates, W. Farr, W. J. Empson, G. Wythes, H. Balderson, F. Q. Lane, G. Reynolds, G. Norman, and J. Willard.

Mr. W. J. Empson, gardener to Mrs. Wingfield, Amptill, staged thirty-eight dishes of Apples. They were very good in quality, and well preserved. The best dishes were Peasgood's Nonesuch, Lord Derby, Bismarck, Smart's Price Arthur, Wellington, American Mother, Mère de Ménage, Prince Albert, Gascoyne's Scarlet, and Cox's Orange Pippin (silver Knightian medal). Mr. Hislop, Bletchley Park Gardens, Bletchley, exhibited a good dish of Russet Apple The Scotsman. Mr. J. Miller, gardener to the Right Hon. Lord Foley, Ruxley Lodge, Esher, staged a basket of Mushrooms (vote of thanks). Messrs. J. Christmas & Co., Worplesdon, Surrey, forwarded a dozen bottles of fruit wine, which were sampled by the Committee, who passed a vote of thanks to the sender.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. C. T. Druery, J. H. Fitt, H. J. Jones, H. B. May, R. Dean, G. Stevens, W. Howe, J. Hudson, J. Jennings, J. F. McLeod, C. J. Sizer, G. Gordon, C. E. Pearson, C. E. Shea, J. T. Bennett-Poë, J. D. Pawle, Chas. Blick, H. Turner, E. T. Cook, George Paul, and Chas. Jeffries.

Mr. F. Miller, 110, Fulham Road, South Kensington, exhibited an extensive display of floral decorations. The flowers employed were Narcissi, Tulips, Lily of the Valley, Roman Hyacinths, white Lilac, and Freesias. The exhibit was very bright and attractive at this period of the year (silver Banksian medal). Messrs. Barr & Sons, King Street,

Covent Garden, exhibited a first-class strain of blue Primulas; the flowers were large, well fringed, and a good colour. Messrs. F. Sander and Co., St. Albans, contributed a group of *Acalypha Sanderi*, which were very bright, interspersed with the *Acalypha Godseffiana* and *Dracæna Sanderiana*.

Messrs. Jas. Veitch & Sons, Chelsea, staged a box of their Rhododendron Javanico-Jasminiflorum hybrids, comprising the forms Thetis, Souvenir de J. S. Mangles, amabile, Diadem, multicolor, Ruby, Ceres, Sybil, and Mrs. Heal. The same firm also staged baskets of *Skimmia oblata*, well berried; *Skimmia fragrans rosca*, and *Skimmia fragrans*; also well berried plants of *Skimmia japonica*. Large pans of *Davallias intermedia*, *Mooreana*, and *deccora* were also staged from Chelsea. Mr. Peter Blair, gardener to the Duke of Sutherland, Trentham, exhibited a pan of *Saintpaulia ionantha alba*. Messrs. Hugh Low & Co., Enfield, sent a plant of *Gerbera Jamesoni* in flower. Mr. R. B. Leech, Wood Hall, Dulwich, exhibited a large vase of *Asparagus deflexus*, which was well berried. Mr. H. Squelch, gardener to E. Speyer, Esq., Dorking, staged a white *Chrysanthemum* named Elaine Squelch.

ORCHID COMMITTEE.—Present: H. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, T. W. Bond, S. Courtauld, R. B. White, H. Little, F. Sander, J. Gabriel, H. Ballantine, H. J. Chapman, W. H. Young, F. J. Thorne, H. T. Pitt, E. Hill, W. Cobb, J. Douglas, H. M. Pollett, and de B. Crawshay.

Messrs. Jas. Veitch & Sons, Chelsea, showed a very pretty and interesting group of Orchids, staged in their well known style. The chief features were well-flowered specimens of *Cymbidium Traceyanum*, the old *Oncidium ornithorhynchum*, *Lælio-Cattleya Dominiana langleyensis*, *Lælio-Cattleya* × *Pallas*. The pretty little *Dendrobium Endocharis*, *D. Cassiope*, and *Cypripediums Creon*, *Leeanum*, *C. Lecanum giganteum*, *Euryades*, and *Niobe* (silver Flora medal).

Messrs. B. S. Williams & Son, Upper Holloway, exhibited a beautiful group of *Cypripediums*, which comprised a great variety of well grown forms. The following were the most notable—*C. Leeanum superbum*, *C. Measuresianum*, *C. nitens*, *C. insigne Wallacei*, *C. Pitcherianum*, Williams var., *C. Sallieri*, and *C. discolor* (silver Banksian medal). Messrs. F. Sander & Son, St. Albans, contributed a small group of Orchids, which included *Cattleya Trianae* var., *C. Harrisoniae* var., well flowered plants of *Phaænopsis Smartiana* and *Oncidium Rogersi*.

CERTIFICATES AND AWARDS OF MERIT.

Angræcum Veitchi (J. Veitch & Sons).—A hybrid between *A. eburneum* and *A. sesquipedale*. A very fine cross, the sepals partaking the colour of the pollen parent, the petals almost white, and the lip a clear satiny white. The long spur of *A. sesquipedale* was reduced by one-half. A silver Flora medal was awarded the raiser for the first cross of the *Angræcum* (first-class certificate).

Cypripedium Schlegelianum superbum (N. Cookson).—A very beautiful form, the petals and dorsal sepal heavily spotted with deep crimson (award of merit).

Cypripedium bellatulum, *Dulcote* var. (W. Cobb).—A remarkable form; the petals and dorsal sepal are blotched with deep crimson (award of merit).

Epi-Cattleya Mrs. Jas. O'Brien (J. Veitch & Sons).—A hybrid between *Epidendrum O'Brienianum* × *Cattleya Bowringiana*. The flower is purple-rose throughout and very distinct (award of merit).

Lælia anceps rosefeldiensis (De B. Crawshay).—Sepals and petals dark rose purple, petals overlapping the sepals; lip dark, outside side lobes white, disc of lip pure white, tube deep purple (award of merit).

Odontoglossum Ruckerianum Rochford's variety (T. Rochford).—A very fine form, the petals are heavily barred with cinnamon (award of merit).

Sophranitis Rossitima (W. H. White).—A very bright orange colour throughout (award of merit).

EELWORMS.

In the *Journal of Horticulture* of the 23rd of June, 1898, page 521, there appeared an exhaustive and very able article by Mr. G. Abbey on the action of silico-fluorides on crops and pests. The subject was of special interest to me at the time, as I had been much troubled by the ravages of eelworm. I, therefore, determined to try the effect of the silico-fluoride of ammonium in the manner suggested by Mr. Abbey.

I had a border, 10½ yards by 13 feet, which had been prepared for Tomatoes. I had used it before for this crop, but, owing to the prevalence of eelworm, with poor results. I obtained 2 bs. of the silico-fluoride, dissolved it in 32 gallons of rain water, and watered the border with the solution. The Tomato plants (160) were then put in and grown in the usual way. I am bound to say that the crop I obtained was a great improvement on the preceding one, although on pulling up the plants recently I observed that the eelworms were not all gone. Still, I have formed the opinion that another dressing of the silico-fluoride would have the effect of completely destroying them.

As this substance, like other insecticides, acts by contact, it would perhaps be better to use a weaker solution—say, half ounce to a gallon of water, and to apply the quantity in two waterings instead of one, turning over the soil between the operations. For plants in pots a very weak solution is essential. I found that the liquid I used was too strong for a plant in a 24-size pot, which was killed by it. This fact will give a good idea of the powerful action of the salt.—M. POYSER Cheshunt.

GROUPING PLANTS FOR EFFECT.

WHAT TO IMITATE AND WHAT TO AVOID.

HAVING dealt, on pages 15 and 16, with several points that ought to be strenuously avoided, I now turn my attention to items worthy of imitation, and naturally these will largely be the opposites of the points previously noted. However, there are a few things that should be mentioned. The first consideration must be a good background—that is to say, something more natural than canvas or a painted wall. Canvas with the light shining through has a bad effect, and no matter how closely together the plants may be placed, some of this will be seen. I have tried many things—natural bark laid on the boxes in which the plants have been brought, and built up to form a rustic screen, and a moss screen made in sections, and both have been found effective. If there is any credit attached to this I may, without conceit, claim it, for until such backgrounds were made by myself I never saw one; but evidently the idea has caught, for it is common now to see it done. Even in this case do not do the same thing too often. I never have had two alike, and see no signs of dearth of ideas yet. Water has a lovely effect when it can be used rightly, but avoid a fountain, or, as some have done, two little fountains, one at each side at exactly the same distance, and both sending their sprays the same height. No; let us have a dripping well, a miniature cascade—something like we see in Nature. There must be nothing mechanical, and whatever is associated with water let it harmonise, such as Reeds, Mosses, Bamboos, Aroids, and aquatics.

Quality of plants is sometimes ignored in grouping, and it has been said that almost anything will do. It may be admitted that a skilful hand will sometimes beat a man at arranging for effect who has ten times better material, but then a man could do a long journey on an old-fashioned boneshaker, though he could do it much quicker and better with the latest pneumatic. Always endeavour to place each plant so that it seems to be at home. A plant of a shade-loving nature should not hang over a gandy neighbour whose colour has been drawn from the sun. Wherever a plant is put let it look natural. I have seen beautiful sprays of flowers, which would arch like some miniature rainbow, tied up to the very point to straight stakes, or twisted round and round until they look like a floral football. I like to see both plants and flowers left as much as possible to themselves. Of course it is necessary sometimes to use stakes, but let it be done so that while keeping the leaf, shoot, or flower where they are wanted, the natural contour is preserved.

It is wonderful how much better a plant will look by perhaps moving it only a few feet. It was placed, and somehow did not please, but let it be moved and in a moment you say, "That's it! Why is this? In the first instance there was something clashing with it. Some may say, "What is meant by that?" It might perhaps be described as a parallel with a case of two clever men meeting in an assembly and both wanting to shine, and it need not be added that under such circumstances things as a rule do not work smoothly, and often neither is seen at his best, which would not have happened if only one had been there. So with plants, both in flowers and foliage, there must be a sort of sympathetic blend—a gradual toning off, in colour and form. No harsh, sudden jumps from one thing to another, and no two grandly grown plants, looking as though each thought itself better than its neighbour. Everyone must be aware many of our leading exhibitors have taken this point into consideration, for sometimes one may read their thoughts, when making their groups, which would perhaps be something like this, "Now, my friend, I do not want to cause any jealousy between you and that party who is in charge of the other corner, so I must lower you a quarter of an inch, or he will not like it." Corners? forsooth! Why corners at all? I found fault at the beginning of my paper with the old house-roof fashion, but really the present style may become quite as monotonous.

I think if our schedule framers would help us, we might remedy this and a great many more things, which are nice sometimes, but are becoming a trifle stale. I promised in the early part of my paper to say something about the makers of schedules, and hinted that to them we must in the future look principally for improvements in our exhibitions. Great deeds have been done in the past by promoters of shows towards making exhibitions more attractive. For my own part I would alter the arrangements of exhibits, both in putting them in different positions and different forms every year. What is more discouraging to the mind of the visitor than to know what he is going to see before he gets to the place? A remedy might be found for all these faults of monotony; and for the groups I would suggest that the roughest piece of ground be chosen, and if it is not naturally rough dig it out, and make one year dells, another year rough banks. In some fields they are already there, and in many others might be easily made. Lay water on for the use of the exhibitors, to do what they like with it; run the groups all shapes, and have pathways in and out amongst them; and in doing so achieve the very desirable object of making the tents more like a garden.

Of course, as I have already said, effect may mean almost anything, according to the ideas and capabilities of the persons asked to adjudicate, but, generally speaking, if the suggestions made above are followed and improved upon little will go wrong, as the principal societies at any rate are particularly careful in selecting the judges.—GEO. WILSON, *Swanland Manor, Hull*.

SPIRÆA JAPONICA.—Clumps of *Spiræa japonica*, after potting, should be kept moist in a cold frame. The roots will commence action, and cause the crowns to burst into growth. Introduce into warmer structures, and force into flower in a strong, moist heat, giving water freely.—S.

THE YOUNG GARDENERS' DOMAIN.

EUONYMUSES AS GREENHOUSE PLANTS.

AMONGST hardy evergreen shrubs there are few so pretty for pot cultivation and greenhouse decoration as *Euonymus japonicus aureo-variegata* and *E. radicans albo-marginata*. The first named has deep green and beautifully bright golden marked leaves, and is the more effective. The foliage of *E. radicans* is green in the centre, and edged with pure white. Both are easily increased from cuttings, eight or ten of which may be placed in a 5-inch pot, in some peat and sand. They will root in a close frame at nearly any period of the year.

Immediately the cuttings are rooted they should be potted singly in 3-inch pots, the compost consisting of equal parts of loam and peat, with an addition of coarse silver sand. As soon as they begin to root into this there is no danger of them suffering from exposure, for when placed in the greenhouse they soon begin to make progress; and when quite small are extremely useful for edging stages. Plants in 3-inch pots will attain the height of 15 inches and 6 inches through, and when this size is reached, if desirable they can be transferred to 5 or 6-inch pots. The same compost should be used at this and all subsequent pottings. *Euonymuses* may be potted at any time and returned to their old quarters, as they do not require to be kept close and shaded, like many plants after potting. New roots are produced freely, and on this account large quantities of water are required in the growing season. Splendid specimens can be grown in 10 and 12-inch pots, while larger pots and tubs may be requisitioned if desired.

The variety *E. japonicus aureo-variegata* has a good natural habit without any training, though sometimes the leading shoots may require a stake. Side shoots that are inclined to straggle from the line of the others may be tied into a vacancy or cut back. The bottom growths seldom fail to extend in proportion to the main shoot going upwards, and of course the leader may be stopped at whatever height is desired. Pyramidal form is the best. *E. radicans albo-marginata* has a trailing or climbing habit. It hangs over the sides of the pot, and in this style looks very pretty. It may also be made to assume a pyramidal shape by attention to staking and tying through the growing season.

Both alike are subject to become infested with aphids. Occasional syringing does much to remedy this, and is the best way of keeping the foliage clean and healthy. When well grown the *Euonymuses* make conspicuous objects for decorative use, and fully repay any attention in their growth. They are not sensitive to a few hardships, and for either greenhouse, conservatory, or porch decoration always prove their usefulness.—INTERESTED.

THE CULTURE OF FOLIAGE PLANTS.

WITH what satisfaction does the gardener—yes, and his subordinates—enter the plant stove and gaze in admiration on the clean, healthy collection of foliage plants. The culture of foliage plants is one of extreme interest, and to some rather difficult. But what can be more interesting than to watch and attend to the gradually developing growth, the brilliancy of increasing colour, until the plant or collection of plants stand before us, objects of rare beauty in themselves, and calling forth admiration from all who inspect them.

CROTONS.—These rank amongst the most popular foliage plants, and their many good points, both in colour and usefulness, certainly entitle them to a prominent position. The main object to be attained with regard to *Crotons* is short stout growth and brilliant colouring. If they can have a house devoted entirely to their culture so much the better, but where that is not possible grow them in the most exposed position in the stove. Plenty of moisture, both at the roots and in the atmosphere, is essential, and on no account shade them, with the exception, however, of freshly rooted or newly potted plants, and then only for a few days until they have made a start.

Propagating is effected in two ways—namely, by cuttings and ringing. Insert the cuttings in small pots in light soil, and plunge in a warm propagating case with a temperature from 75° to 80°, and keep close for a few days. When rooted they may be potted into 3-inch pots, and for some purposes, such as table decoration, edging the plant stove, and other purposes, this size will be found large enough. When this is the case, and the pots are full of roots, feeding may commence, gradually at first, increasing the strength of the manure water as the plant becomes stronger and more robust. When larger plants are required pot as often as necessary, but avoid overpotting, as weak growth is the result. A suitable compost for *Crotons* is loamy turf, leaf soil, half-decayed cow manure, charcoal and sand added. Some of the best varieties for general purposes are *Prince of Wales*, *Warreni*, *Laingi*, *Chelsoni*, *Readi*, *angustifolius*, *Newmani*, and many more.

DRACENAS.—These are very useful and ornamental foliage plants. Some of the hardier varieties—such as *D. indivisa*, *D. congesta*—are valuable, especially in winter, as they take less harm in cold passages than some of the tenderer varieties. There are several methods of propagation. The more usual mode is to take off the top and root it in a pot; then cut the stem in pieces, taking care that there is a bud to each division. Lay these in a pan of cocoa-nut fibre refuse and sand, damp slightly, and put in a good bottom heat. When rooting and growth has commenced, and the plants are large enough, pot into small pots in light, moderately rich soil, and pot as often as necessary. Ringing is also resorted to by some growers, and is a fairly successful method. It is a good plan to shade these slightly in sunny weather, as they are liable to scorch if water happens to lie on the foliage. *D. terminalis* is rather an

old variety, but still very useful. *Dracenas Goldiana*, *pendula*, *elegantissima*, *Bausei*, and *Cocperi* rank amongst the choicest varieties.—E. J. B.

(To be concluded.)

FRUIT FORCING.

Vines.—*Earliest Forced in Pots.*—The heat about the pots must not be allowed to decline, but bring the fermenting materials up to the rims, pressing them down, yet not so as to raise the temperature above 70° to 75°. A heap of Oak or Beech leaves and stable litter should be in the reserve ground, to admit of a supply of prepared material being obtained as required. When the Grapes are set thin the berries carefully, supply liquid manure to the roots, and place some turves, grass side downwards, around the rims of the pots, so as to form a dish, the turves extending over the rims and resting on the fermenting material, and fill the dish with decayed manure. This will encourage surface roots, which will extend to the turves over the rims of the pots and into the fermenting material, and thus greatly assist the Grapes in swelling.

Early Houses—Exercise great care in ventilating, as sharp northerly and easterly winds, with cold draughts, injure the foliage, causing it to become stunted and crumpled, but judicious ventilation is essential to sturdy growth and well developed foliage. A confined moist atmosphere, on the other hand, causes the growth to become lean and drawn, the leaves thin and poor in texture, therefore liable to be scorched by the sun and fall a prey to red spider. Attend to disbudding and tying down the shoots before they touch the glass, being careful not to displace them from their sockets or cause them to snap by too sharp bending and too tight tying. Stop the bearing shoots near two joints beyond the show for fruit where the space is limited, but where there is room for lateral extension allow a joint or two more, and then let the growths extend so that an even spread of foliage fully exposed to light will be insured, yet avoid overcrowding, as that is fatal to satisfactory results. Remove all surplus bunches, and when they come into flower maintain a day and night temperature of 70° to 75°, with a decline, however, of 5° through the night, and a rather drier atmosphere.

Houses to Afford Ripe Fruit in June.—There must not be any further delay in starting the Vines intended to produce Grapes at the time named. If the roots are partly inside and partly outside, the latter border must be protected with leaves or litter, so as to prevent the soil being frozen, but this ought to have been attended to in November. Supply the inside border thoroughly with water, but only to make the soil evenly moist, as excessive waterings in the early stages hinder root formation, and tend to induce sappy growth with shanking later on. If the Vines are weak supply liquid manure, not too strong, after the border has been made fairly moist. Sprinkle the rods twice a day, depressing young rods and canes to a horizontal level or below, so as to insure the buds breaking evenly. Maintain a temperature of 50° to 55° at night and on dull days, advancing to 65° from sun heat, continuing those heats until the buds begin to swell, when gradually raise the night temperature, so as to have it 60° by the time the Vines come into leaf, and to 65° by day artificially.

Vines from which the Grapes have been cut.—The sooner the Vines are pruned now the less danger is there of their bleeding from the wounds when the sap rises. It is a good plan to dress the cuts with styptic or patent knotting or French polish whilst they are dry, so as to close the pores of the wood, as a safeguard against bleeding. Cut to a plump bud as near the base as possible, two buds being sufficient to leave where the wood is stout and short-jointed, but where the practice has been followed and not proved satisfactory, the operator may prune to the best bud on well-ripened wood. This will cause the spurs to become long, and a shoot must be trained from the base to displace each spur after its shoot has borne fruit. Thoroughly cleanse the house, washing the glass with clear water, the woodwork with disinfectant soap and a brush; limewash the walls, and remove the loose bark from the Vines, avoiding peeling and scraping that may injure the live bark, and wash them with a solution of caustic soda and commercial potash (pearlash), 1 oz. each, to a gallon of water, applying with a brush carefully and not excessively, or use some approved insecticide. Surface-dress the borders, clearing off the loose surface, using fresh loam, with a handful of sulphate of potash, and a 6 inch potful of steamed bonemeal to each barrowload of loam. Keep the house as cool as possible to secure complete rest. If there are plants in the house only afford fire heat to exclude frost, not exceeding 40° to 45° by artificial means.

Late Grapes.—These are best cut with all the wood that can be spared, and the ends of the shoots placed in bottles of water in an inclining position in a Grape room, dry fruit room, or an empty room from which frost is excluded; but not warm (above 50°), or the Grapes will shrivel. This will admit of the Vines being pruned and the house being cleaned, and it is much better than allowing the Grapes to hang on the Vines, pruning having to be deferred until a late period, whereby the latter are liable to suffer through bleeding and want of rest. Maintain a temperature of 40° to 45°, with a dry atmosphere in houses where Grapes are

hanging, and avoid a close atmosphere when the weather is favourable for ventilation. Examine every bunch frequently, and remove all decayed berries.

Strawberries in Pots.—The earliest plants must not be pushed too rapidly, especially in severe weather, 50° to 55° at night being sufficient for those that were started at the beginning of last month, and 60° to 65° by day; but it is better to err on the safe side, therefore 5° less in the absence of sun, the weather being cold, is advisable. Scrutinise the plants closely, and if any aphides are found fumigate the house so as to destroy the pests before the flowers appear. Mildew sometimes fastens on the opening buds; in that case dust with flowers of sulphur. Place more plants on shelves in Peach houses, or in vineries started about this time. The pots should have the drainage rectified if necessary, the surface soil removed or freed of moss or other matter, and be washed clean. A top-dressing may be given of rich material—say, horse droppings—rubbed through a half-inch sieve, with a handful of a mixture of three parts steamed bonemeal and one part sulphate of potash (mixed) to each peck of horse manure. La Grosse Sucrée, Royal Sovereign, Vicomtesse Hericart de Thury, and President are excellent varieties for introducing now. Noble and Auguste Nicaise are also suitable.

THE KITCHEN GARDEN.

Seed Sowing.—If the weather keeps mild and dry long enough for the surface of the ground to dry, many gardeners will be tempted to commence seed-sowing. If, however, previous experience is any criterion, this will mean so much labour and seed wasted. There is time yet for a severe, long sustained frost, and in any case the soil below the surface is far too wet and cold to promote seed germination. Early in February is quite soon enough to sow Peas, Beans, Spinach, Lettuce, Radishes, and other seeds in the open or on warm borders, especially in the case of the heavier retentive soils. In the meantime raise Peas and Broad Beans under glass for planting out on warm borders with a view to having early crops.

Lettuce.—Plants raised in the open to stand unprotected through the winter are in such a forward condition that only a moderately severe frost will cripple and probably destroy them wholesale. A considerable number of plants might, weather still permitting, be planted thickly in hand-lights or under bell-glasses and cloches with advantage. Moving them would check the growth, and the protection afforded would carry them through a moderately severe spell of frost. In order to be on the safe side, sow seed of Cos varieties thinly in boxes, placing these in gentle heat and not far from the glass. In this way a number of sturdy plants, which may be hardened for early planting out, will be available.

Forcing Lettuce.—Cabbage Lettuces such as Early Paris Market, Golden Queen, and Commodore Nutt, force readily. The finest hearts are obtained with the aid of mild hotbeds and shallow frames, but excellent produce may be had by planting in boxes of rich, loamy soil, and placing these in structures where a gentle heat is maintained. Sow seeds at once, this whether a stock of autumn-raised plants is available for early forcing or not, thinly in pans of light loamy soil, and place in gentle heat to germinate. When the plants are well up raise them to near the glass, still keeping them in gentle heat, and be careful not to injure them by syringing. Quite small plants succeed well dibbled in where they are to grow. Six inches of good light loamy soil with a fine surface, over a gentle hotbed, is all the preparation needed for either early or successional Lettuces. Seeds of Cos Lettuces may be sown now thinly in boxes of good soil and placed in gentle heat to germinate. Before the plants become drawn move the boxes to shelves near the glass in a warm greenhouse, where, if properly looked after, the plants will attain to a serviceable size.

Mustard and Cress.—With Endive failing and Lettuce not forward enough to cut, there is all the more need to grow Mustard and Cress extensively and well. Moderately rich perfectly fresh soil is necessary for these small saladings. Sow the seed thickly on the surface of the previously well-moistened soil, press it in evenly, but only cover the Mustard seed, and that very lightly. Place the boxes in a forcing house, or in a temperature seldom below 60°, and cover with mats or brown paper, not reducing this heavy shade till the salading is about 2 inches high, with a view to having long well blanched stems, such as are produced by market growers.

Early Tomatoes.—Plants raised late last autumn and now in small pots ought to be moved into their fruiting quarters at once. A light position and a well heated house are essentials, early Tomatoes succeeding well in the narrow span-roofed houses, in which Melons and Cucumbers are usually grown. They may either be placed in 11-inch or 12-inch pots, arranging these along the fronts, or be planted 12 to 15 inches apart in a narrow square-topped ridge of soil. If there are wooden front stagings over hot-water pipes, cover the woodwork with slates, placing on these a thick layer of ashes. Pot firmly in a moderately rich loamy soil, to which a sprinkling of Vine manure or bonemeal is added; the plants to be trained straight up the roof trellis, and confined to a single stem. Water sparingly at first, taking care, however, not to allow the old ball of soil and roots to become quite dry. A temperature of 55° to 60° by night, with an increase of 5° to 10° in the daytime, according to external conditions, is suitable.

Sowing Tomato Seed.—If seed of a free-setting early variety is sown now, the plants resulting should produce ripe fruit in May. Sow the seed thinly in pans of light soil, and place in a brisk heat to germinate. Raise the young plants well up to the glass, and when the second pair of leaves is well advanced place the plants singly in 2½-inch pots, sinking them to their seed leaves. Under this treatment sturdy plants are soon available for planting out or shifting into larger pots.

THE BEE-KEEPER.

PROTECTION OF ENTRANCES.

BEES wintered in the open air, as is the prevailing custom in this country, are liable to be affected by the many changes in the weather at this season, as it is somewhat difficult to keep the bees at an even temperature. Many apiarians are tempted to close the entrance to their hives during the prevalence of high winds or blinding snow-storms. We do not agree with this plan. Not that any harm would happen to the bees if the entrance were re-opened directly the storm was over; but there is always a danger of this being neglected, and for this reason, if no other, we do not recommend its adoption.

SHADING THE ENTRANCES.

Although it may appear somewhat out of character with the weather to speak of shading hives at midwinter, it can with advantage be done from now onwards. It is the close attention to the details of management that makes the successful bee-keeper, and it is as necessary at this season as at midsummer.

We never under any pretext close the entrance to our hives. But shading from the direct rays of sun is successfully practised. There are various ways of doing this, either by placing a mat, sack, or something similar, over the top of the hive, and allowing it to hang well over the front. This will have the desired effect, as the bees will not be tempted to leave their hive during a spell of bright weather when the temperature is low. Another advantage derived by using a covering in this form is the protection afforded during a heavy fall of snow, as the snow falls quite clear of the floor board, which is thus kept comparatively dry, and after the storm is over, if the covering is removed bodily and well shaken, there will be no snow adhering to the hive. The coverings may again be replaced if necessary. There is nothing more penetrating than melted snow, and stocks often suffer severely from dampness in the hive owing to the snow being allowed to gradually thaw instead of removing it the first opportunity.

Another very simple plan we practise to obstruct the light, but not the air, and prevent the snow from being driven in at the entrance, is done by using a piece of wood or slate placed in a slanting position against the entrance. Whatever is used for this purpose should be slightly larger than the open entrance, and if placed in the right position will have the desired effect. It should be so fixed that any bees which may by chance leave their hive will be able to return.

SECURING ROOFS.

It is useless to expect bees to winter well unless the roofs are made secure, as it is quite a common occurrence for them to be lifted off the hives and blown some distance away during the prevalence of high winds. When this happens during the night, and is followed by a heavy downpour of rain, the interior of the hive will become saturated before the bee-keeper is aware of it. If the roofs have hinges and are fastened to the body of the hive, the wind will have little effect unless the hive is blown over. But the majority of hives are made so that the roof lifts off bodily.

There are various ways of securing them, either by passing a strong cord round under the floor board, and fastening it securely over the roof, or fasten a brick at each end of a strong cord, pass it over the roof, and allow the bricks to hang clear on each side. If the hives stand singly, and are not on a stand, a peg driven into the ground on each side, and a cord passed over the roof and fastened to the peg at both ends, will have the desired effect. Or if the roof is not span-roofed, a couple of bricks placed on the top will answer the same purpose, and all will be well.—AN ENGLISH BEE-KEEPER.

HOW ENGLAND IS SUPPLIED WITH HONEY.—English bees are unable to produce as much honey as England needs. Every year we have to import 2,250,000 lbs., of which the declared value is £31,000, or about 3½d. per lb. Among the countries engaged in supplying our markets with this product the principal are the United States, Chili, and Peru, the other contributors including the British West Indies, France, Australasia, Canada, Germany, Italy, and the Spanish West Indies. No statistics of the quantity of honey produced in the United Kingdom are obtainable, but it is quite evident that bee-keeping is capable of being much more profitably developed than it is.—("Westminster Gazette.")

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Vines in Outside Borders (E. B.).—We should await a season's experience before taking any strong action. Somewhat old Vines in outside borders often succeed very well without lifting, though when confined to limited areas this may often be done with advantage. We should encourage more lateral growth so as to strengthen the Vines, but only so far as it can be done by full exposure of the foliage to light, then you would get better bearing wood and plumper buds. If pruning has not been done leave a bud or two more than in the orthodox method. Apply a top-dressing of some approved Vire fertiliser now, and feed liberally during the growing season, but above all things avoid making the soil sodden, and mulch lightly in advance of drouthy weather.

Neapolitan Violet Leaves Diseased (W.).—Yes, we can tell you that the spotted and curled-up appearance of the leaves is caused by a disease in the plants, a parasitic fungus, *Peronospora Violæ*, which has been unusually prevalent this season, especially in localities that suffered in the summer from drought. This is a characteristic of the parasite, the weather following the dry period, being moist, inducing soft young leaves upon which the spores germinate and enter with great rapidity, causing the spots and collapse. It also affects the flower buds, causing them to damp off or dry up. We have not found anything to act better than removing the worst affected leaves and burning them, then sprinkle dust charcoal freely over the plants and bed. The charcoal seems to dry the moisture and benefit the plants. We have also used a mixture of freshly burned chalk lime, ground to a powder, and flowers of sulphur in equal parts, dusting over the plants very lightly by means of a sulphur duster, or improvised article formed of an old worsted stocking. The disease appears to die out as the days get longer and the weather brightens. It is favoured by a dull and moist condition of the atmosphere, and especially by fogs.

Corrosive Sublimate Solution for Eelworm (F. W.).—Corrosive sublimate solution 1 oz. to 6½ gallons of water, is quite sufficient to kill eelworms, or any other micro-organism, if the infested plants are subjected to it for one and half hour. Flower-pots would be "disinfected" by one part of the poison to 300 parts water; but we do not advise it, as the pots will hold a considerable quantity of the solution, and would not be over-safe to handle. Why not scald the pots in a tub with boiling water? No eelworms will stand that, and while being quite safe would answer your purpose. Certainly half a pound nitrate of soda to 1 gallon of water will kill eelworms—we are not sure about eggs—in soil, not, of course, containing any growing plants. We found 2 ozs. to the gallon of water kill eelworms in soil, and even 1 oz. to the gallon, the former in about forty minutes and the latter in nearly four hours. Kainit, however, acts more promptly and effectively; but many preventives and remedies fail through their not being used thoroughly, so as to reach the eelworms. Besides, kainit is only about one-fourth the cost of nitrate of soda, and there need not be any difference in the amount supplied. Boiling water in actual contact with eelworms will kill them, and we suspect cook the eggs too. Our correspondent says, "Your readers may be glad to know that we find 'fostite' to be the best powder for mildew or rust on Chrysanthemums, or disease on Tomatoes. We distribute it with the 'Malbec' bellows, and its exceeding fineness makes it adhere well to foliage and prove economical in use." It has been advertised in our columns.

Deformed Mushrooms (H. C.).—The fine fleshy Mushrooms are infested by a fungus, *Icaria intricata*, but there are also traces of *I. citrina*. It affects the gills, where the reproductive organs are located, and destroying these parts, the Mushrooms cease growing and dry up. We have known the crops of Mushrooms rendered useless by the pest; generally, however, it affects them in patches here and there. In some seasons it proved very troublesome, and then would disappear for years. The best preventive of the disease spreading was found in keeping a sharp look-out, and promptly removing any Mushrooms that remained stationary and had mouldy gills, burning them. Possibly the disease occurs through the Mushrooms not having a due supply of chlorine, and benefit has resulted from the use of a little common salt in watering, 1 oz. to a gallon of water, not using it over the "buttons." The Mushrooms are not suitable for culinary use, being too dry, and probably not wholesome, but upon that point we have no experience, as we never troubled the cook with them—almost for certain rejection.

Climbers for Back Wall and Ends of Greenhouse (S. B. T.).—We presume the roof of the span with ends facing east and west is partly covered with climbers in the usual way—that is, a plant to each rafter—and the growths so disposed as to afford some light to the plants beneath, so that a considerable amount of light will fall on the back wall. Then the following will be suitable:—*Hibbertia dentata*, yellow; *Lapageria alba*, white; *L. rosea*, rose; *Lonicera semperflorens* minor, scarlet and yellow, sweet scented; *Plumbago capensis*, blue; and *Rhychospermum* (*Trachelospermum*) *jasminoides*, white, sweet scented. As the first named has unpleasantly scented flowers, to which some persons object, you may have *Proustia pyrifolia*, white, instead if considered advisable. If the back wall be very much shaded you will be best served by *Camellias*, which do splendidly and, notwithstanding the fashion against them just now, are the "queen" of the greenhouse in winter. For the ends *Jasminum azoricum*, white; *J. gracile* (*simplicifolium*) var. *De Poiteau*, white. The latter should be given the warm end of the house. If you want a yellow *J. odoratissimum* would be suitable.

Chrysanthemums for Christmas (W. B.).—Little's soluble phenyle can be procured from Messrs. Little & Son, Doncaster, who are the makers. In regard to a supply of good white Chrysanthemums at Christmas, the contributor to whom you appeal writes, "I can confidently state that there is really no great difficulty in securing them. In the Midlands the seasons are fully ten days later than in the South, so that by following the same general course of treatment such a variety as *Niveus*, which you state was over with you by the second week in December, would by a little attention to retarding, be in full beauty at Christmas in the Midlands. We had a good number of this variety in 48's, which were all sold in the pots, on December 24th. The cuttings were inserted during the first week of April, stopped when they were about 6 inches in height, and then allowed to grow at will. The mild autumn gave us the opportunity of leaving the plants in the open air till the third week in October; they were then placed in a late vinery, and received just enough fire heat to exclude frost and damp. Larger plants for supplying cut flowers were produced from cuttings inserted in January, and stopped as required till the second week in July. The whole of the flowers from these were cut during the last two weeks of December. *Princess Victoria* and *Lady Canning* naturally flower later than *Niveus*. By inserting cuttings of these at the present time we have no doubt they may be flowered during the last two weeks of December, and well into January anywhere in the South. We have plenty of both varieties whose flowers will not be fully expanded till a fortnight hence."

Apples, Pears, and Plums for Appearance (J. S.).—Your beautiful district, so far as we have seen, does not appear favourable for hardy fruits of the nature indicated, and this is, we apprehend, the reason of the generally high prices that we have observed in the shops. The atmosphere may be too humid for the maturation of the wood, and the trees cannot have the thorough winter's rest that is so good for them in the absence of anything like severe frost. We think you will find interest in variety, and noting the climatic effects on such as those we will name. In no other way can you find the special adaptability of certain varieties for the positions in which you desire the trees to flourish. We strongly advise that they be thinly trained, or the branches thinly disposed, and if there is a tendency to luxuriance in any or all of them, to dig up and replant biennially, or as the nature of the growth suggests, until a sturdy, fruitful habit is induced. The soil should be firm, but only making it so when in a moderately dry state, as any serious amount of compression when very wet is injurious. If it is deficient in calcareous matter, basic slag applied at the rate of ½ lb. or more per square yard of surface, and mixed in to the depth of a foot, would be likely to act beneficially. The following are worth trying: Apples for BUSHES—*Dessert*:—September Beauty, Lady Sudeley, Worcester Pearmain. *Dessert or culinary*:—Duchess of Oldenburg, Cardinal, Cox's Pomona, Gascoyne's Seedling. *Culinary*:—Cellini, Yorkshire Beauty, Golden Noble, Emperor Alexander, The Queen. Apples for WALL CORDONS—*Dessert*:—Red Astrachan, American Mother, Allington Pippin, Cox's Orange Pippin, Scarlet Nonpareil. *Dessert or culinary*:—Washington, Wealthy, Buckingham, Lewis's Incomparable, King of Tomkin's County. *Culinary*:—Bismarck, Beauty of Kent, Brabant Bellefleur, Warner's King. PEARS for bushes:—Beacon, Madame Treyve, Emile d'Heyst, Beurré Clairgeau. Pears for cordons against wall: Souvenir du Congrès, Louise Bonne of Jersey, Durondeau, Doyenné du Comice, and Pittmaston Duchess. PLUMS for bushes:—Belgian Purple, Victoria, Prince Engelbert, Washington, Monarch. Plums for cordons against walls:—Denniston's Superb, De Montfort, Early Transparent Gage, Jefferson, Kirke's and Coe's Golden Drop.

Bullfinches (R. A. C.).—Your letter has been forwarded to Mr. J. Hiam, though as he is much from home anything like a prompt reply may be impracticable.

Tomatoes (A. Geary).—Where several varieties of Tomatoes are grown, it is difficult to keep the stocks true, and this may account for the variation in your case. The fruits also are, to some extent, influenced by methods of culture, some growers producing all varieties of larger size than do others. Our correspondent "H. D.," who is a successful grower, found Sutton's Eclipse to produce ideal fruits for market—medium sized, smooth and round—and if it succeed as well this year as it did last season, he will be likely to grow it still more extensively.

Destroying Black Ants (J. S.).—As you have tried to exterminate them "with bones," not sufficiently persevered in to effect the object, and "also used sugar mixed with calomel," which is best used in spring, you may find the following preparation useful; but it must be employed with the utmost caution, as it is a poison fatal to animal life. Recipe: 1 oz. of ordinary or white arsenic and $\frac{1}{2}$ lb. of Demerara sugar. Place the arsenic in an old iron pot with a quart of rain water, and then boil over a gentle fire until reduced to a pint or a little more of liquid. Add the sugar and mix well. The "syrup" can be dropped about the runs and haunts of the ants, or it may be placed in saucers near their nests. The ants will gradually disappear, some time being necessary to effect a clearance.

Scale on Apple Tree Bark (Young Grower).—No, the scale is not *Aspidiotus* or *Diaspis ostreiformis*, but *Mytilaspis pomorum*, commonly called Apple mussel scale. Yes, petroleum "burns the bark" in some cases, and "if it is diluted it does not kill the scale." The best means of destroying the pest is the old-fashioned potash and soda lye, which dates back to the time of Herodotus, and now used in the handy form termed Coate's solution of caustic soda and commercial potash. For your purpose 1 oz. each of those substances may be dissolved separately or each in half a gallon of boiling water, then adding the two solutions together and mixing: apply with a clean half-worn paint brush when cooled to 130°. It suffices to wet every part of the bark thoroughly, but not lavishly, so as to run down and cause injury by an over-application. Take care not to exceed the strength—1 oz. each to a gallon of water. The trees should be dry and quite dormant when dressed.

Currant Bud Mite (T. D.).—The shoots are badly infested by the Currant bud mite (*Phytoptis ribis*). If all the buds on your bushes are swollen we are sorry to say they cannot possibly be restored to their original condition by the application of anything whatever, because nothing can reach the mites inside the buds. The bushes must either be dug up and burned, or cut down and the tops burned, following in the latter case with a very heavy dressing of lime. We once cut some down, the branches in this case springing from beneath the soil, and spread a thickness of half an inch of lime or more on the stumps and soil. We scarcely expected to see any further growth from the stumps; they, however, pushed freely, and in two years produced abundance of fruit, and not a swollen bud was subsequently seen on the bushes. Had they been on clean stems a foot or so above the soil the results might have been different, and we know that some cultivators have not found the cutting down and liming to banish the enemy. When attacks are comparatively slight, some cultivators syringe their bushes when dormant with a mixture of sulphur and lime, to render them distasteful to the mites, and then watch for and pick off every swollen bud in the spring, burning the buds removed, and in this way decimate the pest. Burn at once all seriously infested branches, also the buds from those less infested, in case there are sufficient unattacked buds for affording some fruit. Do not propagate from the bushes, but obtain young trees from an undoubtedly clean stock, and plant as far distant from the infested bushes as possible. This is more important than some growers appear to realise, as the mites have undoubtedly means of locomotion, which they requisition to travel from one plant to another, and even very much greater distances than that. Swollen buds and the destructive mite have more than once been illustrated in the *Journal of Horticulture*.

Peach and Nectarine Trees Casting Buds (F. J. B.).—The buds are not "deaf"—that is, without central formations corresponding to the flowers, though some of them are defective, and appear to have been dead a considerable time. We have grown Peaches and Nectarines in lean-to houses facing south-east and south-west, and have found the trees were less prone to bud-casting than in structures with a due south aspect. The bud-dropping appears due to over, rather than under ripening, as they seldom fall from outdoor trees on walls, unless pinched for water in the growing season. Are the trees in too light and loose soil, subject to changeableness of moisture and consequent check on the buds at times during their formation? This experienced gardeners consider the chief cause of Peach and Nectarine trees casting their buds, and it is consonant with our experience. We have had the greatest success with the trees in sound firm soil to which has been applied a mixture of superphosphate five parts, sulphate of potash two parts, and sulphate of magnesia one part, using 4 ozs. persquareyard during the resting season, and pointing in lightly. The best of all preventives of bud-casting we have found has been lifting the trees carefully, laying the roots in fresh compost near the surface, and making quite firm, so as to promote stout wood and a vigorous root-formation. Then the soil will be more retentive of water supplied and of the available nutrients, and under good management the trees retain the buds and produce fine fruit. The buds sent appear to have been coated with some substance, but of this you make no mention, and it may, or may not, have been injurious. See remarks on lifting Peach trees, by Mr. Backhouse, on page 33.

Various Plants (J. C. S.).—*Eurycles Cunninghami*, or Brisbane Lily, has white flowers, grows about a foot high, and requires a warm greenhouse. It is a handsome bulbous plant, and requires water withheld for a few weeks after growth is completed, so that the bulbs may ripen and rest. *Sandersenia aurantiaca* is a pretty, tuberous-rooted, erect-growing herb, with simple leafy stems, and a native of Natal. It requires an open soil composed of loam and peat in about equal proportions, affording good drainage. The bulbs should be started, after careful repotting, in February, in a temperature of about 70°. Warmth and moisture are necessary in summer, but as the growth ripens, water should be gradually withheld. During winter the soil must be kept quite dry, and the pots laid on their sides in a warm greenhouse. Exposure to cold when at rest is a point specially to be avoided. It is a liliaceous plant allied to *Gloriosa*. *Zephyranthes carinata* (fig. 8) is a greenhouse or half-hardy bulbous plant

FIG. 8.—ZEPHYRANTHES CARINATA.

from Mexico. The flower scape grows about 1 foot high, the flowers have a green perianth tube, and the segments are pink and about 2 inches long. The plant grows and flowers in summer, and rests in the winter. It should be grown on a sunny shelf in the greenhouse. Compost turfy loam, with a leaf mould or well decayed manure and a free admixture of sand, repotting about every two years. *Ada aurantiaca* has orange scarlet flowers, in a long terminal raceme. It requires to be potted in peat and sphagnum in equal parts. The drainage must be perfect, and during summer the water supply profuse. Although in winter far less will suffice, yet the plant should not be allowed to become too dry; indeed, it must never be entirely rested. It is a pretty species, and lasts a considerable time in beauty; but though easily grown does not always flower freely, probably from being kept too sparingly watered when making growth, the pseudo-bulbs not acquiring sufficient strength. It requires to be grown at the warm end of a Cattleya house or a cosy corner in a warm greenhouse. With strong pseudo-bulbs the flowering is not difficult, and the time being winter and spring renders it desirable in collections. It is one of the easiest grown of Orchids when a suitable position is found for the plant.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (T. R. B.).*—Your specimen more closely resembles a finely grown fruit of Galloway Pippin than any other variety which we know. (D. W.).—1, Annie Elizabeth; 2, Spencer's Favourite; 3, Yorkshire Greening; 4, Wadhurst Pippin; 5, too shrivelled to permit of positive identification; 6, Langton Nonesuch. (A. B. C.).—1, New Northern Greening; 2, Golden Winter Pearmain; 3, Wormsley Pippin.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (Journeyman).—All forms of Cyrtopodium insigne, and not one of them is of special merit, though all are useful for home decoration. (L. W.).—1, Dieffenbachia picta; 2, Croton angustifolius. (S. S.).—1, Oncidium tigrinum; 2, Lælia anceps; 3, Cymbidium Lowianum. (D. C. B.).—1, Tradescantia zebrina; 2, Adiantum cuneatum grandiceps. (W. T.).—The Zonal Pelargoniums can only be named by comparison in a large collection.

A SHORT REVIEW OF 1893.

We do not like to write these words, they sadden us. With us more years can now be written off as gone than we can possibly hope to see again. They go so fast now. We write of winter, and lo! we have spring. We tell of summer flowers, and they fade before our ink is dry. We do not get through half we plan during the long days of sunshine, and the longer winter evenings still leave us with uncompleted work on our hands.

From many points of view this last year has been an extraordinary one—especially as regards cold. We have always been led to expect a certain amount of cold weather; we mean really cold—good old fashioned frost and snow, and we hope for it. Much as some of us dread wintery weather, there is a real necessity for it. Weather can do what man with all his machinery cannot. We rejoice to see the ice-bound roads—we rejoice to see the frozen clots—we smile at the abundant mantle of snow, for we feel these are powers silently at work on our behalf.

But last year there was nothing of this to record. Two or three sharp days in the middle of December made our 1898 winter. Day after day passed mild even balmy, with little or no rainfall, and excess of sunshine. We think (but have no written records to go upon) that this last has been an unusually windy year. From every quarter the wind came, and paid lengthy visits. If we had no winter we had some coldish summer days—days when we were glad to sit over a fire. We would rather the cold came in short days, when at least the shutters can be put up early and the cheerful fire and lamp impart a ruddy glow on our surroundings.

It does not seem quite the thing to sit over the fire when the Roses are ready to bloom, and the young Gooseberries cry out for a gatherer, but so it has been. We did get hot weather and plenty of it, when we began to wonder if old England had not made a trip to the tropics, and when the great heat had gone, a genial warmth followed us up right on to Christmas week, just to be broken by a sharp frost of short duration.

To judge of this last year properly, we ought to go back to the autumn of 1897. A wonderfully fine growing season it was, and consequently we began 1898 with plenty of herbage in the fields, and a grand root crop. An abundant winter supply means great ease of mind to the farmer. The difficulty in spring was to get rid of the roots in time to sow Barley, and good sound Swedes were to be begged on every side. We do not say we had too many Mangolds over, that we cannot have as long as there are yards full of pigs, but we almost fancy this time a few got wasted. Potatoes, too, of good varieties, made a wonderful finish, and put some good money into deserving pockets. There was also a short "boom" in Wheat, but alas! few of us had any left in store, and the prices fell and fell.

Such a haytime as we have to record! Plentiful rains gave grass a good push in the spring, and the crops were magnificent, and got in such excellent order. Hardly a bit of "old cow" hay anywhere; all fit for fast galloping horses of the Shires. There has been a general complaint respecting the scarcity of labour, and many farmers have had a real difficulty to face. During hay time, in one village we wot of, the mother of a duchess was undertaking the horse raking, and every servant and member of the household were pressed into the service of securing the dried grass.

A dry season suits the Wheat crop, which had an excellent start the previous autumn, and got away finely. In some low-lying districts we heard much complaint of laid crops, but taking the country as a whole we must write the Wheat crop as a success. The weather was too dry for the best Barleys, many of which were thin and rather flinty; but the Oat crop did well. We have heard of record yields; and not only is the corn so abundant, but the straw, being well ripened and healthy, makes the most excellent of fodder.

In the southern and eastern counties the long drought had a most disastrous effect on the Turnip crops, but further north the farmer has nothing of which to complain. "Smothered with fly," was the cry, and a very serious business it was. We heard of whole—and many of them—fields from which the sheep turned away loathing. Where this was the case it was also found that the pastures were perfectly bare, and the poor farmer was fairly at his wits' end to find suitable, or indeed any, keep for his flocks; and this just at a most critical period, when lambs are too apt to go altogether wrong, and when the ewe flock needs a stimulating diet. Happy were those men who had some low-lying land with a good Rape crop, or those whose Cabbage patch was what it should be.

The drought also proved a serious impediment to autumn ploughing. The ground was like iron, and resisted the iron of the ploughshare, and it required a good deal of rain to make the land at all workable. This was in startling contrast to many autumns we have known, when all work was delayed by unwearying rain. The question is, Which kind of season is most injurious? and it is a question which is not easy to answer. Many of us were in serious difficulties re our water supply; but at the same time we were with thankfulness reviewing the excellent season we had for storing roots and pieing Potatoes.

Ah! well, there always will be two sides to every question, and we should not be British agriculturists if we could not get in a small grumble somewhere. Taking the year as a whole, our crops of corn, roots, hay, and Clover have been good, and were prices a little better we should think there was a return of the prosperity of thirty years ago.

This has been a disappointing year to the large Midland grazier, and indeed to all those whose occupation is to provide the butcher with matured meat—foreign competition! Store stock has been much dearer in proportion than fat. This is quite the wrong way about, and what profit can there be for the grower of prime Christmas beef when he only realises 7s. per stone. Think of all the cake, the dried foods, the hay and Clover that have to be consumed to make even one stone of good beef. We have long failed to see how the thing was done. It is like conjuring, and the secret is hidden in the breast of the owner. Best mutton, too, at 8s. per lb. does not mean anything

very grand, though we think pork at 6s. per stone would be cheaper "ficed" for a family.

The dearest class of stock just now is a good cow in full milk, and a really good cow commands an excellent price. For the winter season calves are dear, quite making £2 at a week old. We do not mean a wretched little Jersey or any fancy breed, but a good large variety, such as a Shorthorn Hereford, or the like. We have always advocated rearing calves instead of buying in casuals from any market or fair. There is less liability of imported disease, and a well fed calf never gets stunted or thrown back in its growth, and in early maturity is the only chance of making any profit at all.

WORK ON THE HOME FARM.

Frost, snow, sunshine and rain on one and the same day, give us variety and change enough in all conscience; but a good deal of moisture has fallen, and notwithstanding the fact that some low-lying lands have floodwater on them, the water is very welcome with a view to next summer's supply.

A really thorough frost we are apparently not to have, and we want one badly; much muck is ready for removal, but the surface of the land is too soft to cart on, and though the roads are much improved on what they were a few years ago, manure-leading would soon make bad work with them in their present soft condition. Meanwhile we keep the ploughs at work, otherwise the horses would have to stand in the stable.

The Potato trade lately has been very stagnant, and few are being removed from our district; but we hear of others being almost denuded of them, so perhaps the consumption may have been heavy; a sharp frost would help to clear the markets and brighten up the trade.

Farmers complain much of the poor prices made of Christmas beef, and no wonder, when we hear a large butcher owning up that his beasts bought at the Christmas markets, forty in number, only cost him 5½d. per pound. There must have been a great profit for somebody, for little beef is sold under 6d., all the best cuts for 9d., and there is all the offal besides, which at one time would have easily realised £5 per head.

Wheats are growing fast, but the larks are still paying attention to the later sown plots. We have seen some green shoots 3 inches long lying on the surface, having been uprooted quite lately. We see a neighbour carting salt from the station, which reminds us that soon will come the time for sowing it on the young Wheat. Farmers do not use salt so much as they once did; the price of Wheat no doubt has something to do with it. But the raising of prices by the Salt Syndicate caused many farmers to give up using salt, and few of them have recommenced.

The voice of the chicken is heard in the incubator the nineteenth day. This evidently intends to be an early bird.

REMARKS.

- 1st.—Foggy morning; rain from 4 to 6 P.M.; clear night.
- 2nd.—Overcast early; rainy from 8.30 to 11 A.M.; bright sun from 11.30 to sunset; showers from 5 P.M., and gale at night.
- 3rd.—Gale in small hours; fine day, frequently sunny, and bright sun from 11 to noon.
- 4th.—Rain till 1 A.M., then dull and humid; sunny from 10 till noon, and occasionally after; spots of rain in evening.
- 5th.—Slight fog early; sunny almost throughout the day.
- 6th.—Overcast, with occasional slight drizzle.
- 7th.—Overcast, with spots of rain early; sunny from 10 to noon; overcast again after.

A damp week, temperature high, but not remarkably so.—G. J. SYMONS.

BARR'S SEED GUIDE FOR 1899 IS NOW READY,

And will be Forwarded Free on Application.

BARR'S SEED GUIDE contains a Select List of the best Vegetable Seeds and most beautiful Flower Seeds. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. SENT FREE ON APPLICATION.

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS contains a liberal assortment of the following useful vegetables: Beans (Broad and French Beans), Beet, Borecole, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrot, Cauliflower, Celery, Colewort, Corn Salad, Cucumber, Cress, Endive, Herbs, Leek, Lettuce, Melon, Mustard, Onions, Parsley, Parsnips, Peas, Radish, Salsify, Savoy Cabbage, Scorzoner, Spinach, Tomato, Turnip, and Vegetable Marrow.

Other Collections of Barr's Vegetable Seeds, 5/6, 7/6, 12/6, 42/-, 63/- and 105/-. These Collections sent carriage paid on receipt of remittance. Full particulars on application.

BARR'S CHOICE FLOWER SEEDS.—Our Catalogue contains a Select List of all the most beautiful Annuals and Perennials. Special Collections for all purposes, and many Sterling Novelties.

All Seeds sent Carriage Paid on receipt of remittance.

BARR & SONS,

12 & 13 King Street, Covent Garden, London
Nurseries: LONG DITTON, SURREY

| 1 " Couve Tronchuda | 2 " Scorzoner |
| 4 ozs. Cress | 6 ozs. Spinach |
| 3 Pkts. Cucumber | 6 Pkts. Herbs |
| 2 " Egg Plant | 2 " Tomato |
| | 4 ozs. Turnip |
| | 1 Packet Vegetable Marrow |

For other Collections from 10/- to 100/- see our Seed List
Orders for VEGETABLE SEEDS of 20/- and upwards sent Carriage Paid.
Orders for FLOWER SEEDS of 3/- and upwards free by Post.

LIST will be sent post free on application to their Offices at OVERVEEN, nr. HAARLEM, HOLLAND, or to their General Agents,

Messrs. MERTENS & CO.,
3, CROSS LANE, LONDON, E.C.

No. 969.—VOL. XXXVIII., THIRD SERIES.

NOVELTIES RAISED AT WINDSOR AND OSBORNE.

It is Messrs. CARTERS' privilege to offer the following new and choice productions to the notice of gardeners and private cultivators.

BRITISH QUEEN MELON.

Raised and named by Mr. OWEN THOMAS, Supt. of the Royal Gardens, Windsor. Awarded the First-Class Certificate R.H.S. Pronounced by the Committee to be not only the very best white-flesh melon ever submitted, but the richest flavoured of any colour. Awarded the Gold Medal of the Royal Caledonian Society in association with other fruit exhibited by H.M. The Queen.

In sealed packets, price 2/6 and 3/6 each, post free.

ROYAL OSBORNE CUCUMBER.

A valuable cross between the Rochford and an improved type of Telegraph, raised and named by Mr. GEORGE NOBBS, Head Gardener to H.M. the Queen at Osborne. In our opinion it is one of the best all the year round varieties introduced in recent years.

In sealed packets, price 2/6 & 3/6 each, post free.

ILLUSTRATED CATALOGUES, POST FREE.

CARTERS,

The Queen's Seedsmen.

Only Address—

237, 238 & 97, HIGH HOLBORN, LONDON.

The 32nd Edition is Now Ready.

200 PAGES. 150 ILLUSTRATIONS.

PRICE SIXPENCE, POST FREE.

(By Parcel Post—it is so large).

EVERY AMATEUR SHOULD POSSESS A COPY.

CONTENTS.—The Best Seeds and Potatoes for Garden and Farm; also Descriptive Lists of Carnations, Chrysanthemums, Dahlias, Fuchsias, Gladioli, Herbaceous Plants, Pansies, Pelargoniums, Phloxes, Pinks, Pyrethrums, Roses, and Violas, with full Cultural Directions for each.

BLACKFORD.—"The postman with your Spring Catalogue and Competitors' Guide was my 'first foot' this morning. It is without doubt the best and most useful publication of any I come across, and should be in the hands of everyone possessed of a bit of garden ground. Thanks! Thanks! Thanks!"—J. McG.

DUNDEE.—"The woodcuts in your Catalogue are excellent, and altogether it is beautifully got up."—A. H.

LEICESTER.—"I received your Catalogue with thanks. It is a very useful work for amateurs, and none should be without it."—H. S.

WELLINGTON.—"I have to thank you very kindly for your beautiful Catalogue you sent me. It is the most compact and instructive Catalogue I ever read."—J. P.

Apply Early, and please mention this paper.

AN ABRIDGED EDITION OF OUR CATALOGUE CAN BE HAD FREE ON APPLICATION.

DOBBIE & CO.,

SEED GROWERS AND FLORISTS TO THE QUEEN,

ROTHESAY.

Journal of Horticulture.

THURSDAY, JANUARY 19, 1899.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

A LOST CHORD.

FENN AND FUNGUS.

I, on page 490, I read "An Old Provincial" right, between his lines, he seems to miss the lively "humour" that shined and sparkled through our olden time compositions in the *Cottage Gardener*. I should find it difficult to harp on the same string over and over again, with fine phrases, long drawn out in correct calligraphic flourish, which distinguish for the most part the gardening columns of the *Journal of Horticulture*. No "eminent editor" would pat me on the back for an elegant flow of rhythm; nor, lacking the rest, would it help me to carry out experiments towards keeping a "pot a-boiling" for the future.

"An Old Provincial" has, however, resuscitated for me a conversation that happened in Piccadilly with my good old friend Donald Beaton, a short time before his death, in regard to "humour." Beaton—we thought him recovered, or nearly so, from a sad affliction—was wending his way from Chiswick Gardens, where he had attended a meeting of the R.H.S. Committee. I saw he appeared agitated and perturbed, and inquired of him what had happened. "They have been telling me my writings are all chaff." "Oh," I answered, "is that all; come and have some refreshment with me (we were just opposite the then Wellington dining-rooms, where I was bound for); it is only their way of talking, and, after all, where can you fail to find a modicum of chaff in a good sample of wheat?" He smiled, but my gloss scarcely satisfied him. He did not enter the restaurant, for he said he had not long before partaken of (the then) R.H.S. hospitality. Poor Donald! I never saw him again, for he was not long afterwards interred in Kingston Churchyard, to rest, to sleep, and be out of it all.

He was endowed with rare "humour," was Donald, and had expressed chagrin to me before because of the editors striking out his choice bits—of course wrongfully. Alas! too, for my phenomenal self! However, in the midst of fighting he hanged to writing. I want to describe for you now a tussle I have had amongst the "Mums."

No. 2625.—VOL. C., OLD SERIES.

Three years ago you, Mr. Editor, came to see me along with another young man who has since visited the Midnight Sun, and lately been footing it in the United States of America, and for all that I know he will circumambulate the globe before returning to us. You may remember how he felt surprised at the abundance of foliage I allowed on my Tomatoes, and made a start to lop away a portion of it at once. "Not so, on any account," I struck in; "it is the pride of my life to maintain it so in all its integrity, as well also as you can see upon the Potatoes and other things; thanks to Tait, Buchanan, and Peter Barr's anti-blight powder." I did not then say that I was touring about my district some few weeks before preparing a report of the fruit crops, that I noticed something uncanny in a few places upon the foliage of Chrysanthemums. I was not a grower of the flower.

When I erected my Potato seedling house here I enlarged it to become dignified to a "greenhouse," and caused three iron pillars to be placed to support the extended glass roof. To furnish these I sowed to run up them and look pretty Nasturtiums mixed with Canariensis. But the stricken foliage I had observed upon Chrysanthemums caused a premonitory feeling with me that we should hear of it much farther afield. Anticipating, I begged a few cuttings from a neighbour whose plants were suffering. I would plant them against the pillars for a change, and for a purpose, to test what effect the anti-blight powder might have upon their foliage to prevent it from becoming diseased. Those who have cared to read my experiments with it in these pages, or those of my visitors who have published their observations, and learnt our good opinions of its qualities in preserving leafage, while annihilating fungoids and immatured insect life, will be in a measure prepared for what I am going to say.

Well, to secure the desirable effects, the anti-blight powder should, in a glass house, be applied early in January onwards, and fairly continuously through the succeeding months, in dry impalpable condition, by the agency of a Malbec bellows. It is then and thus the benefit is secured. The powder will not injure the tenderest foliage or the most delicate flower if not applied too bountifully; on the contrary, infantile shoots thrive under it, and for those of older growth the leaves soon become robust in their greenery without any syringings with water, at least, they do so with me in my Potat—I beg its pardon, my greenhouse, where I grow Grapes, Figs, Tomatoes, seedling Potatoes in their first stages, herbaceous plants, and now Chrysanthemums. I have also lately had under the glass, from the outside, Roses and Honeysuckles, to prove what effect the powder may have upon those implacable harbourers of aphids, mildew, and red spider, under cover.

This *multum in parvo* house has only the ground for a floor, which of necessity must be watered, otherwise I have purposely desisted from syringing the wall, the wood and glass work, the Vines, or any foliage in the structures, during a period of five years. As a rule, I think too many splashings about under glass unnecessary—a mere rule of thumb. I wish I could prevail upon my good old chum, "A. D." to draw out of that Bourdeaux-Bordelai rut for drier compost. With his greater suasion his friends would soon learn to bless him. To return: I applied the powder as above to the Chrysanthemums; they retained their foliage intact, feathered completely down to the ground, and flowered beautifully.

This behaviour of them against the pillars urged me to procure cuttings from a distance in greater variety, to be grown in pots. As soon as they were placed they were made to undergo the bellows' pepperings, and so on through their rooting stage and other two shifts or pottings, and outside-sentry-go, as is usual. I ought, though, to mention the soil's nature that I grow them in. It is procured from off my garden experimental Potato plot, a fairly good loam, from a site whereon was burned a heap of collected debris—tree prunings and other combustible matter. This is cooled by distribution with a rake during the charring process, to secure the potash, by preventing the sticks of wood as charcoal wasting away to grey ashes. Whilst it is quite hot about 2 inches of the surface soil is shovelled up to become stored away, and afterward mixed with the cooled sprigs of

charcoal, thus making sure that all there was of living insect life is dead, and we get a lasting easy compost, in which we do not hesitate to grow most things. Results: I pin my faith to the mystic number three. I believe I have never given any of my experiments off for these pages under a three years' probation. This three years' trial obstructive of "rust" deposit on Chrysanthemums gives me hope that the same agreeable circumstances may happen for others, should they feel inclined to work after the manner I have pointed out.

I have read many queries and remarks in contemporaries: Your own in issue November 3rd, 1898, page 343; Mr. G. Abbey's intensely absorbing scientific researches, December 13th, pages 284-5; and, with great pleasure, Mr. Massee's, on page 286-7 of the same issue of the *Journal of Horticulture*. Mr. Massee's remarks are more accordant with my homely researches than anything I have previously met with; they mostly agree with what I have observed and written about for the last six years or so in regard to my Potato disease spores, which float or become dispersed, imperceptibly to the naked eye, in warm weather and bright sunshine, to rest, if they can, upon the surfaces of congenial foliage. But where these are powdered over with the anti-blight the microbes, or whatever the scientists properly call them, cannot meet with this destination otherwise than by the penalty of instant death; *per contra*, they would insinuate between the cuticles into the pabulum, to quickly mature, and from the under sides cast their spores on to the surfaces of the leaves below to become their prey, or to be dispersed by the air or some sportive syringe in their billions round.

I must not dwell much longer on the subject or I fear you to say that I am "swamping" you. I will beg room for another paragraph *à propos* to our important and indispensable autumn flower. My friend in Gloucestershire who sent me cuttings had his wife up to place his flowers at the Reading Chrysanthemum Show, whilst he was further afield, for those of Oxford and Banbury. He takes prizes wherever he goes. Feeling interested, his wife came to see my "missus," and the "Mums." She expressed herself delighted, and surprised at their perfect healthiness, as she said she had been obliged to spend nearly all her time in sponging the "rust" from the leaves of the very plants propagated from those from which mine were taken. To clinch this nail, so far as I have driven it, a young gentleman who was staying with our rector having a camera with him, kindly came and "took" the enclosed photo, about the middle of November. It takes in about two-thirds in length of the plants in the greenhouse, but sufficient for you to see the representation of redundant foliage which "feathered" from the surface of the pots upwards. The iron pillars I have pointed out by marks, to show how those plants maintained their *last year's foliage* intact, quite to the ground, as I did not cut them down.

Again—for one moment—I seem to recognise the facile hand of an "Old Provincial" as that of an old contributor (is it Pownall's?), but of course our Editor never divulges incognitos. The paper impresses one how quickly flows a "record" of life in achievements towards old age, and has caused me to write this article for the pages where I introduced myself in 1850. I had not long then—viz., when I wrote, struck thirty-two years of age; I was over head and ears struggling with the 'taties and other problems. I was tolerably well grounded in horticulture, and very soon after my first epistle came a letter from Mr. Johnson, the first genial Editor and founder of this paper requesting me to write some articles, and to send him a specimen. I did, but nervously tried to back away. Another letter to say that "he who could write the paper I had sent could write anything he wanted to bend the printers' backs with, and I was to set about it at once." Thus I became fairly hooked, and ever since I have annually, more or less according to what I have completed, "bent the printers' backs" for these pages, in the City of London, by explaining away some "new thing" anent improvement for the cultivation of our native soil, and in publishing the experiments I have carried out for the betterment of our food, or the beautifying of God's fair earth. But . . . Lord

Nelson said what England expected, and One greater than he asked of old, "What is required of thee, O man?"—ROBT. FENN, *Sulhampstead, near Reading.*

[In recognition of the long connection of our octogenarian contributor with the *Journal of Horticulture*, yclept in its youthful days the *Cottage Gardener*, and of his services to horticulture, especially as the pioneer in the improvement of the Potato by the art of cross-fertilisation, we assign this his latest, but we hope not the last, of his "compositions" the prominent position to which, all things considered, we think it is entitled. As we like to afford a momentary pleasure to the verdant old evergreen, with his good heart, clear head, and busy hand, we have prepared one or two of those "long drawn-out sentences" of the present day for his special delectation, in the hope that he will enjoy them, even if the style is such that ought not to be followed, but eschewed, and this being so it shall be changed forthwith.

The photograph received cannot be reproduced. For this we are sorry. The light at the moment did not permit of the characteristic features of the plants being brought out with sufficient distinctness for clear transference. All the same, the original shows a dense mass of luxuriant foliage from the ground to the roof of the house, and a fine setting for the emergent blooms. The remarkable point, however, to be noted is that the bold leaves hanging over the pots were produced in 1897. Though in perfect health when photographed, they were a year and nine months old. This fact at once affords conclusive evidence of the best cultural attention, and of the complete mastery obtained over the destructive rust fungus.

It is important to remember that the "rust" was prevented, not destroyed. Over and over again we have advised the same action that Mr. Fenn has taken with such gratifying success. We have before stated, and state once more, that we have seen Roses, Vines, Honeysuckles, and other plants virulently infested with mildew at Sulhampstead, also Potatoes, reeking with disease; then on subsequent visits found nothing but greenness, cleanness, and health, except in the case of half rows of Potatoes left untreated.

In the combat between Fungus and Fenn the former had to succumb to the early and systematic measures resorted to, as described, for preventing the enemy taking possession of the plants. This is the safe and sure course for mastering insidious fungoid pests. We wish still much longer life to the victor, and thank him for showing the way, also for affording conclusive evidence of his success in combating fungoid foes. The sub-title of the above heading is ours.]

LONDON GARDENS OVER FIFTY YEARS.

No. 2.

THE memorable year that witnessed the uprising of this Journal and of some other periodicals I need not name, which have largely benefited the world, was, by way of contrast, marked politically by the downfall or dislodgement of many organisations which people thought likely to endure for aye. It is imperfectly represented by pictorial designs, so those who never saw it can form but a poor idea of the London of 1848, as it appears in the recollection of old stagers like myself. One change that strikes us particularly is that there seemed to be, fifty years since, a well defined boundary between the town and its suburbs, now these have been absorbed into the metropolis.

Again, we think how all the metropolitan suburban lines that carry yearly their millions of passengers on pleasure and business bent have seized upon land that was formerly fields or gardens, and such facilities for travelling by train, and by tram also, have brought up in every direction crops of houses where all was open ground surrounding villages, in the early Victorian period. Yet, even in the reign of George III. citizens had begun to migrate to the suburbs, for Cowper mentions the villas which, like an Indian's belt, encompassed London, and he regards them as an indication, not merely of a love for fresh air, but of a desire to possess a garden. Certainly no small number of these mansions, with extensive gardens and shrubberies, of which Clapham and Kensington gave examples, occupied by well-to-do lovers of flowers and fruit, did much for the promotion of horticulture. They have vanished, but the impress of their work abides.

Great indeed has been the revolution in domestic gardening during the last half century. The change is marked not only by the increased number of ornamental plants cultivated, but by the improvement of methods. One cannot help admiring the patience and hopefulness with which people watched over the plants of city gardens, expecting them to thrive in the ordinary soil of London, unaided by natural or artificial manure. The poet just mentioned, referring to the London gardens he had seen, and which were often so airless that he calls them "wells," names Nightshade and Valerian amongst the plants that

were doomed to a city life. I never saw any Nightshade species growing in an old London garden, appropriate though it might be to the gloom of the metropolis, except *Solanum nigrum* as a weed. But I will not say it is unlikely. Some may have had the Woody Nightshade on a garden fence, for the plant used to thrive in hedges just outside London. About the Valerian, no doubt people did cultivate *V. hortensis* and *pyrenaica*, with their respective flowers of red and white, hardy perennials, which required no particular care. There was no telling, however, what plants you might come upon growing amid smoky surroundings. We remember a scene in "Martin Chuzzlewit," where Dickens pictures the dingy room of Mr. Mould, the undertaker. One thing remarkable was that the Scarlet Runners of the small garden, lit up by stray gleams of sunshine, sent in through the window a strange lurid light.

The same author, doubtless from personal observation, has also depicted gardens, then not unusually found attached to a London house, where the inmates had no time or taste for floriculture. We may discover one like it yet, with its solitary tree, two or three perhaps, which put forth leaves feebly in autumn, he says, when other trees shed theirs, and linger on year after year, crackled and smoke-dried. The ground around these is like a piece of unreclaimed land, strewn with tins, crockery, hampers, and rubbish. Possibly a few remnants of Box indicate that an attempt had once been made at a border, and some stunted "everbrowns" are scattered about, while even weeds seem to shun a spot where nobody walks from choice. We may have seen such in Central London or in some suburb, but such mockeries of gardens are rarer now.

There were excuses to be made formerly by their possessors, as fifty years ago people had not the present facilities for obtaining seeds or plants cheaply, nor did they possess the knowledge on gardening subjects which is accessible to all in our popular manuals and periodicals. Another thing we notice which tends to the improvement of gardening in a street or road, is that we often see now a wholesome rivalry. Thus Mr. A makes his little domain showy, and this stirs up Mr. B and Mr. C on each side, so they try to adorn their garden plots. But of course the Londoner has always had to contend with cats and sparrows, with an atmosphere, too, in which smoke and fog combine forces. The limitations of space have generally been hard upon the middle-class Londoner, who occupies a house of from six to ten rooms. His allotment of ground is but small; as a consequence thousands of gardens have been formed on the same model, a border on two or three sides, and a central space of gravel, grass, or simply London clay. Occasionally, where a garden had greater depth or length than the average allowance, one or more middle beds would be formed; these were mostly planted with shrubs, the sides being then devoted to herbaceous plants, or partly sown with annuals.

In 1848 there remained some gardens, even in the thickly populated neighbourhoods, where Pear and Apple trees grew, and occasionally produced fruit, and a Cherry or Mulberry might be found. A few gardens had the centre filled with Currant or Gooseberry bushes, seldom productive, as their insect foes were numerous and diligent. Vegetables have been grown in the back gardens of London streets, but Potatoes or Cabbages seldom; experimenters were fond of trying Peas and Beans, succeeding now and then in getting a small crop. Rhubarb is an esculent which has been raised in very close districts of London.

Scattered on the margin of what was its country border fifty years since were many detached houses, with sufficient garden ground belonging to them for a fair show of flowers and vegetables, often of fruit too, and amongst these we sometimes came upon one having its old style garden of Georgian days carefully kept up. Within the four-mile radius most of them have been removed to make room for houses of a different class. Speaking generally, we may say that there is a tendency all over the suburbs to lessen the gardens allotted to new houses, owing to the increasing value of land. Large slices have also been taken off some of the longer gardens of the past generation, for workshops and other objects. Then there are springing up large blocks of workmen's dwellings and flats, often minus gardens, having only a court or playground. Hence the importance of laying out squares and old churchyards as public gardens, and preserving any vacant spaces yet left in proximity to crowded neighbourhoods. One thing rather surprising is, that when the streets and squares of Belgravia were built, these aristocratic residences got but a small allowance of garden ground, the rear of many being occupied by stables and mews. Of course, the inhabitants have the benefit of an extensive range of parks.

During the last twenty years the erection of large board schools has absorbed some open spaces, and not unfrequently they have occupied the site of an old nursery garden, so that where plants used to be tended, the minds of juveniles are brought now under cultivation, with good results, we hope, though recent accounts of London ruffianism seem to indicate many educational failures. One of Tom Hood's comic designs, illustrating a "Fall of the Stocks," reminds us that

Londoners have long had a fancy for window gardening, and their flower-pots frequently have not been properly guarded on the window-ledge from the effects of wind or accident. It is hard to say which is the more agitated, the good lady who sees her cherished flowers fall to ruin, or the image-seller, amongst whose wares the pots descend with destructive force. Wiser nowadays, people guard against such accidents in the usual way by putting a wire bar, or they have window boxes, not pots; though some had the boxes half a century since, and one plant especially a favourite was *Mignonette*, admired for its fragrance, and supposed to purify the air. May has long been the month when the sale of perennial plants and early sown annuals in pots is particularly brisk about London streets, for the stock of plants is then in need of renewal.

Also, in addition to the window display, there are to be found in thousands of backyards, stands, large or small, with their array of pots. These were formerly conveyed in autumn to a garret or cellar, to reappear after the winter, at least such as survived; but now the Londoner often has a garden frame to hold tender and half-hardy plants, or perhaps he owns a miniature conservatory. One of the metropolitan street cries which has ceased to be heard is, "Buy a bowpot!" What was this? A "bowpot" contained a plant that had the support of a bow of wood, shaped rather like a kite, which might help it to live in the London air. "Geraniums" or *Pelargoniums*, I think, were then in a big majority amongst window plants. Myrtles, of course, have their popularity still, and the *Fuchsia* was spreading abroad. There would be occasionally a *Rhododendron* or *Heath*; some had a fancy for succulent plants, and grew *Cactuses* and *Sedums* in pots.

Londoners at one time could boast of their *Roses*, but the smoke has precluded their culture in the metropolis for many years, and it had so increased as to be hard upon *Tulips* and *Camellias* early in our Queen's reign. But still there remained plenty of old-fashioned perennials for beds and borders, that looked green all the summer, even though they were scant of flowers. It was noticed by Loudon in his time that the mildness of its average winters enabled gardeners to show, even in December, *Larkspurs*, *Violets*, *Gentians*, *Polyanthuses*, and other autumn or spring species.—J. R. S. C.

TOMATO CULTURE.

THE Tomato (*Lycopersicum esculentum*) was introduced into this country in 1596. It is a native of Mexico and South America, but is also found in the East Indies, where it is supposed to have been introduced by the Spaniards. The Malay name is *Tamatte*, and in Mexico it is called *Tamalt* (Dr. Hogg's "Vegetable Kingdom," page 547). It belongs to the same natural order of plants as the Potato—viz., *Solanaceæ*, and is cultivated for the use of its fruit for cooking as a vegetable, as an uncooked ingredient of salads, for making Tomato sauce, and for various other culinary purposes. The fruits, formerly called Love Apples, are sometimes used in a green, but more generally in a ripe state.

When the Tomato, or Love Apple, came into vogue in England as a vegetable I have not been able to ascertain; but Abercrombie, writing in 1788, says:—"The fruits or apples of these plants are, in some families, much used in soups, and are also often used to pickle, both when they are green and when ripe." When I first made acquaintance with Tomatoes they were only wanted for making sauce, the plants being grown against south walls on the vacant space between fruit trees, and in warm situations in favourable localities trained to staked trellises. In 1818 I saw Love Apples thus grown in the open as far north as York, the plants being put out when not more than a foot high, and then very sturdy, short-jointed, in flower, and even setting fruit. They were planted on May 13th a yard apart, and protected on cold nights up to the middle of June. They bore abundance of fruit, and ripened almost, if not quite, as well as similar plants against a south wall.

Another point I have not been able to settle is when Tomatoes were first grown under glass for maintaining a continuous supply of fruit from an early to a late period of the year, or even throughout the whole year. Of course I know Love Apples were grown in greenhouses here and there, partly from fancy, and partly to secure a supply of fruit in cold localities for the desirable sauce. Every cook seemed to need some fruit for this purpose, and, as far as I can remember, no other. "Kitchen servers" have generally good memories, especially when the house is a mile or more from the kitchen garden. There was no such thing in that establishment as growing Tomatoes under glass up to the ripening of the fruit, nor in the up-to-date gardens near by, though the bedding-out craze was at its height, and there were many small houses or pits at liberty from May to September inclusive, that could then, or now, have been utilised for the purpose. After the Great Exhibition of 1851 the taste for everything grown under glass developed

at an enormous rate, and now and again houses of Tomatoes were to be seen in various parts of the country, until they became quite general, and after 1870 a number of establishments sprang into existence in which Tomatoes were cultivated on a vast scale under glass.

Tomatoes can be had from January 1st to December 31st—a big stride from the August to October supply, as commonly produced half a century ago on south walls. Tomatoes are in shops every day in the year, and it is a question of the home grower or the foreigner producing them. That is just the difference—an outdoor climate pitted against under glass cultivation. Taste, of course, has to answer for this, though not being content with the supply as had from walls and the catering for it by growing the fruit under glass. I know many walls are still devoted to Tomatoes, but both they and the fruit trees have gone under glass to a very large extent.

In the good old times—8s. a week and bothy for a growing lad far on in the teens—there were no eelworms at the roots of Tomato plants, and no Love Apples with scabbed faces. The plants were grown "hard," and they defied all their enemies in the soil and in the air. The cultivators knew very little about fertilisers, save the substantial "muck," handy lime and tell-tale soot, with a little guano. Salts, except common, were hardly known in gardens, yet the plants were healthier, and produced as good or better crops than now they are forced out of health and into disease.

Professor A. H. Church, F.R.S., in his "Food" says that Tomatoes "require good soil and abundance of water," with which I do not culturally agree, for the more water the more "rot." But I can appreciate his analysis of the Tomato as an article of food, and give the public taste credit for the free consumption of such healthy and wholesome food.

Ripe Tomatoes contain in 100 parts:—

Water	89.8
Albuminoids, &c.	1.4
Sugar	6.0
Malic acid	0.7
Cellulose and pectose	1.3
Mineral matter	0.8

The nutrient value of the Tomato is more than twice that of the Vegetable Marrow, and it contains malic acid, which is said to be good for the "brain." Yet how the asylums multiply! People must really eat more Apples—*Pyrus Malus* vars.; and Love Apples—*Lycopersicum esculentum* vars. How to produce the latter will follow, for there is no reason why anyone having a fair garden should not grow Love Apples for his household. There will always be plenty of growers for market. Thus ends the preamble.—G. ABBEY.

(To be continued.)

THE LONDON FRENCH HORTICULTURAL SOCIETY.

THERE was a large and enthusiastic muster of members and supporters of the above named Society on Saturday evening last at the Imperial Restaurant, Strand. Mr. Drost of the Kew Nurseries occupied the chair, and was supported by the presence of several English friends of the Society. After the dinner was over the President of the Society, Mr. Geo. Schneider, introduced the Chairman, and touched briefly upon the progress of the Society.

Ms. Drost said it was an honour to occupy the chair on the occasion of their tenth annual dinner, for looking back in the past there was every ground for great satisfaction, for the Society, which began in a small way, now numbered something like 500 members in all parts of the world. Their library, which began with only twenty volumes, now consisted of 120, many of which during the past year had been rebound. Notwithstanding this and other expenses, they could congratulate themselves upon having £22 more in the bank than they had at this time last year. Much of this success was due to the devoted and active efforts of their good friend Mr. Schneider, and he would ask them to drink to his health, and this was done with a burst of enthusiasm. Mr. Schneider replied, and looking round the room said he was gratified to see so many English friends present, and he would ask them to drink to the health of the visitors.

Immediately following this, Mr. Guilloud arose to make a presentation of an electroplated *cafetière* to Mr. Schneider as a mark of esteem on the part of the members. This was suitably acknowledged, and then Mr. Arnold Moss responded in a humorous vein for the visitors. He felt sure these gatherings did an immense amount of good, and he assured his young French friends that the wish of the English people at large was to see France happy and prosperous, and the two countries on the most friendly terms, expressions which evoked the heartiest acclamations. Mr. Gachelin proposed the English Horticultural Press, to which Mr. Harman Payne briefly replied, saying that, although he was not a professional journalist, he felt sure that the English Press took a great interest in their Society, and would help it on in its useful career.

THE GARDENERS' ORPHAN FUND.

If "Annual Subscriber" had referred to his copy of rules governing the Fund's management, he would have found that the Secretary can be appointed only by the members at the annual general meeting, and that the office is but of annual duration, as that official has to submit himself for re-election yearly.

Naturally, the subject of filling the office vacated by Mr. Barron was the primary one discussed at the recent Drill Hall meeting, and on every hand I found a consensus of opinion in favour of the election being by ballot. Still further, it was held that the Committee should severely refrain from nominating any one person, but, there being four or five selected from the entire body of candidates, their names should be printed on a ballot paper, and copies handed round to each subscriber present, who should vote by putting a cross against his favoured candidate, the papers being collected by scrutineers and counted, no paper being accepted other than those collected in the room. Each paper should be signed by the subscriber, but only as a guarantee that he was entitled to vote.

It is but natural that there should be much anxiety to secure for the post the best possible candidate, and one who is not only familiar with the Fund, but one who has been a worker and helper in it in the past, and who is essentially identified with gardening. It is unfortunate that in publishing the advertisement inviting applications it was not made clear that applicants must be associated with the gardening vocation, and not to exceed a certain age; also should furnish a pecuniary guarantee from some acceptable society. These were conditions that would have occurred to any body of good business men. Personal canvassing other than through circulars or cards should have been held to disqualify candidates at once. These conditions would have cleared the ground largely at the outset. As it is, very many persons have applied for the post whose prospects are, to put the matter mildly, ridiculous.

It must not be forgotten that for the work, which is largely, after all, formal and regular, not spasmodic, is well remunerated with £100 per annum. As was remarked at the Drill Hall, it is "a decidedly good screw." It ought to secure the loyal services of a first-rate man; too much care cannot be taken to prevent any sectional or mere market appointment. The selected official should be a thoroughly honourable man, having the confidence of all sections of subscribers. I hope before promising votes every subscriber will await the decision of the selection committee, and even then do so only on mature consideration.—A. D.

CAN it be true that the selection committee, or whatever it may be called, appointed to examine the applications for the secretaryship and report thereon, consists mainly of what are known as Covent Garden Market men? If so, it cannot be fairly representative, and if there happen to be an able Covent Garden candidate, some of the members can scarcely feel themselves in a pleasant position in the conscientious discharge of their duty.

Several growers of produce for market have been good supporters of the Fund during recent years, and some have been, and are, useful members of committee, but the founders of the Society were private gardeners and pressmen chiefly, who took the responsibility and shared the anxiety and work in establishing it. This being so, it is but reasonable that they should be represented on the reference committee as well as the horticultural trade and market men. It is hoped they are, though reports say they are not, and if not it is a pity.

It is no secret that among the numerous candidates are men of undoubted capacity, intimately connected with gardening and the gardening press, as well as with secretarial work—men who have been strenuous workers for the Fund, some of them over many years. If these men are not adequately represented on the examining committee it cannot be so complete as it ought to be. It may be granted that the members will act honestly and fearlessly, still it does not appear to be altogether appropriate that certain sections of the horticultural community should be practically ignored.

The rumour was current at the last R.H.S. meeting that amateurs were represented on the Committee by the Chairman, Mr. W. Marshall, traders by Mr. Weeks, and everybody else by Messrs. Assbee, May, Poupart, and Walker, marketers. This may not be a complete list; whether it is or not, neither a private gardener nor press representative was mentioned at the Drill Hall, and the assumed omission was thought strange by more than one.—MEMBER, BUT NOT A CANDIDATE.

HAFODUNOS.

THIS, the seat of Colonel Sandbach, is situated in the County of Denbigh, North Wales, and its nearest railway stations are those of Llanwrst and Abergele, which are respectively seven and eleven miles distant. This fact no doubt explains why Hafodunos has so seldom been referred to in the gardening press, as from a horticultural, and more especially from an arboricultural standpoint, it is quite entitled to take a prominent position. "Hafodunos" is a Welsh word meaning "Rest for one night," and tradition says that the body of St. Winifred rested here for one night on its way to its final resting place at Holywell.

The estate is about half a mile from the pretty village of Llangernyw, on the road from Abergele to Llanwrst, which is about eighteen miles distant, and this road, from beginning to end, was made by and at the sole expense of the late Squire of Hafodunos, who was throughout his long residence a great benefactor to this district.

At the entrance to the park is a commodious lodge, built entirely of stone, and on passing through the lodge gates the visitor at once gets a foretaste of what this place is more especially noted for. There are to be seen on the right side of the carriage road some magnificent specimens of *Wellingtonia gigantea*. Most of them were planted about fifty years ago, and are at the present time 60 feet high. They stand on rapidly rising ground, and all of them are in perfect health and vigour, and each differs in habit from its fellows. Proceeding along the drive towards the mansion we notice many splendid trees and shrubs. The mansion, a most beautiful structure, built some thirty years ago from designs by the late Sir Gilbert Scott, on or very near the site of a former residence, is about 500 yards from the gates.

Near here are part of the ruins of an ancient monastery, and most of us know that in consequence this place must be pleasantly situated and the soil around it generally fertile, for the monks of old were no mean

FIG. 9.—HAFODUNOS.

judges in selecting the best positions for their abodes. We almost invariably find that wherever there is a monastery or monastic remains there is an abundance of good water, good fishing, and good land, where fruit and vegetables can be grown, thus insuring them a constant supply of the good things of this life.

At Hafodunos we see many plants growing vigorously and flowering freely that are only seen in highly favoured localities. On the front of the mansion many of our best and tenderest varieties of Tea Roses grow vigorously, and during the season are covered with flowers of excellent quality. Amongst others there are several large plants of Fortune's Yellow, a most exquisitely beautiful variety, but rarely seen doing well in the open air. On the terrace walls we noticed many climbing plants that in the north and the midlands have to be wintered in conservatories and greenhouses, yet here in North Wales they thrive apace, and year after year are covered with beautiful blooms. Very conspicuous was an exceptionally large plant of *Escallonia macrantha*, covering at least 80 square feet of terrace wall, and full of flower.

At the bottom of the terraces flows a beautiful stream of water, which has cut its way through the hills and rocks, in some places forming quite deep ravines and in others a beautiful dell, or dingle, as they call it there. Along its banks, and in many other parts of the grounds, are superb specimens of the best varieties of *Rhododendrons*, and they must

look gorgeous when in full bloom. Many of the Sikkim varieties are represented by plants 15 feet high by 20 feet through, and these being well backed by magnificent Conifers, interspersed with noble forest trees, must during the summer months form such a grand pictorial display as is only too seldom seen.

Passing along the side of the dingle, we come to a rustic bridge, from which a view can be obtained of a beautifully designed miniature cascade and waterfall. Near here there are many charming bits of rustic scenery, which can be viewed in comfort at nearly all seasons of the year, as this walk is admirably sheltered from both cold wind and summer sun. Its sides are planted with Conifers, Rhododendrons, and many other evergreen and deciduous shrubs, whose stems and branches are almost covered with the beautiful grey lichen. Many of the larger trees and shrubs tower high above us, others far below, even down to the very edge of the stream, and it is a great delight to gaze down upon those marvellous specimens of Pinus and Piceas, all studded with their beautiful cones.

Towards the end of the dingle we reach the kitchen gardens, of which this rivulet runs through the centre, with on each side rapidly rising ground devoted to fruit and vegetable culture. But so sharp is the gradient that at all seasons it must be very difficult to work and crop the land; yet Mr. Jones, the able and experienced gardener, succeeds in producing abundant crops of both fruit and vegetables of large size and excellent quality.

On the walls I noticed some fine crops of Plums, Transparent Gage being well to the fore. In one of the quarters I saw a very large stock of choice Conifers, both seedlings and transplanted stock for planting in different parts of the estate, as Colonel Sandbach is year by year improving his estate by planting large quantities of trees and shrubs, intermixed with many choice Conifers, and it is surprising how well many of the Piceas and Araucarias are doing even in the most exposed situations. This advanced and enlightened practice might with great advantage be copied by many of our large landed proprietors.

The glass department at Hafodunos is not extensive; adjoining the mansion there is a small but very beautiful conservatory, in which are some fine Camellias and Ferns. The walls and pillars are covered with healthy plants of Lapagerias, Tacsonias, Plumbagos, and Passifloras. In the kitchen garden there is a long range of glass devoted to the culture of Peaches, Nectarines, and Figs, which have produced abundant crops of splendid fruit for many years past. Tomatoes, Cucumbers, and Melons were equally well done, and the same must be said respecting such decorative plants as Chrysanthemums, Begonias, and Cyclamens. There is only one large vinery, but the crop was heavy and the fruit of good quality. Near this vinery there is a large unheated structure, which is set apart for the culture of Pears, and many of the large trees in this house were loaded with crops of excellent fruit.

I must now revert to the Coniferæ, for they are the real gems of this beautiful place, and a few particulars respecting their size and history may prove especially interesting to many. The late Squire of Hafodunos was not only a lover and planter of Conifers, but he was a most enthusiastic collector and raiser, and many of the finest and most unique specimens of Conifers were raised from cones gathered by him during his travels from trees growing in their native habitat, and planted here many years ago. The present owner is, like his father, a most ardent and enthusiastic arboriculturist.

Among other Conifers that we saw, the following are the names and dimensions of a few of the best:—

Abies Albertiana, 80 feet high and 7 feet 9 inches in girth at 5 feet from the ground; this is a truly marvellous specimen, perfectly symmetrical and well furnished throughout.

Abies Hookeri, 18 feet high, and Abies Pattoniana, 16 feet high. These two varieties have long been classed as synonymous, but as seen here, growing side by side, they are very distinct.

	Height.	Girth at 5 ft.
Abies Douglassi	70 ft.	8 ft. 10 in.
„ Menziesi	60 „	„
Araucaria excelsa	52 „	5 „ 0 „
Cedrus atlantica	55 ft.	7 „ 0 „
„ libanus	48 „	8 „ 9 „
„ deodara	58 „	„

Sciadopitys verticillata (the Umbrella Pine).—A most unique and perfect specimen, which has borne cones for several years past. It is now about 13 feet high, in perfect health, and growing well.—C. L. Welton, East Yorkshire.

WEATHER IN LONDON.—Since our last impression was sent to the machines the country has been visited by a gale of exceptional severity, and which was attended by serious accidents. This commenced on Thursday, in the afternoon of which rain, hail, and snow fell, with a violent hailstorm about ten o'clock at night. On Friday morning the wild had abated somewhat, and rain fell almost the whole of the day. Saturday brought a change to balmy air and glorious sunshine, while on Sunday morning came a reversion to a downpour of rain, another following on Monday. Tuesday opened fire with heavy rain later, while Wednesday was dull and damp.

— WEATHER IN THE NORTH.—More or less rain has fallen every day during the past week, and sleety showers have been frequent. Snow fell heavily on the morning of the 12th, and the hills all round are covered. The rainfall was especially constant during Sunday and the following night, but the afternoon of Monday was fair and the evening frosty, 5° being recorded on Tuesday morning.—B. D., S. Perthshire.

— MR. DAVID THOMSON.—A correspondent writes:—“I hope that Mr. David Thomson is well. I should be glad to see more of his weighty articles in the Journal. Mr. Thomson always appears to say a great deal in a small space, which is better than saying little in a thousand words.” [Judging from his bold, clear “copy,” which the compositors like as well as we do, we are glad to think that the veteran is in better health than he was some time ago, and is happy in his garden.]

— BRISTOL GARDENERS' ASSOCIATION.—“Chemical Manures, Specially in Relation to the Kitchen and Market Garden,” formed the subject of an address given to the members of this Association on Thursday last by Mr. F. W. E. Shrivell, and the eighty members present were unanimous in voting it one of the most interesting addresses they had ever listened to.—CHAS. LOCK.

— BIRMINGHAM GARDENERS' ASSOCIATION.—The last meeting of the autumn session of this Society was held on the 9th inst., for the election of the officers and Committee for the ensuing year. Professor W. Hillhouse, Mason's College, was elected President; Mr. Joseph W. Oliver, teacher of botany and geology at the Municipal Technical School, Birmingham, being elected Vice-President; Mr. W. B. Latham Chairman, Mr. Walter Jones Vice-Chairman, Mr. A. Gardiner Librarian, Mr. W. Spinks Treasurer, and Mr. W. L. Deedman Hon. Secretary. A favourable financial balance-sheet was produced by the Treasurer. The gratifying addition of several new members during the past year is chiefly due to the influence of the Hon. Secretary.

— SHREWSBURY SHOWS.—The schedule of prizes offered by the enterprising Horticultural Society of Shrewsbury during the present year is now being distributed. The spring show is to be held on April 5th, and consists of thirty-eight classes, twenty-one of these open to all, the remainder to amateurs only. Practically, all kinds of plants generally in full beauty at the time are provided for. The best prizes are £4, £3, and £2, for a collection of twelve plants (Orchids excluded), the same amounts being offered for twelve Azaleas. The summer show, which opens on August 23rd, however, is the event to which horticulturists of the kingdom will look forward with the greatest interest. In the plant section are prizes of £25, £17 10s., and £10 for groups of plants in and out of bloom, similar amounts being provided for non-flowering plants. For twenty specimens the prizes are £25 and £15, and for thirty plants, in pots not exceeding 10-inch, £20, £15, and £10. The chief cut flower class is for bouquets and baskets, for which the prizes are £15, £12 10s., and £10. The fruit section contains a class that will be historic—namely, the £100 class for Grapes. It ought to be a battle of the champions, the blue ribbon being £25 and a gold medal. The decorative dessert table class is worthily included with prizes of £15, £12, and £8, while £10, £7 10s., and £5 are offered for twelve dishes of fruit. Those are a few of the leading classes. Excellent prizes for vegetables are offered by leading seed firms. The show is bound to be one of great magnitude and diversity, seeing that the schedule contains 200 classes. The railway companies will return plants free that remain the property of exhibitors, and the Committee undertake to render all possible help in conveying exhibits from the station to the show ground free of cost.

— **GARDENING APPOINTMENT.**—Mr. W. Owen, general foreman at Madresfield Court Gardens for the past three years, has been appointed head gardener to the Hon. G. H. Allsopp, M.P., Foston Hall, Derby, in succession to Mr. G. Lewis, who retires from gardening, and takes up farming in March next.

— **HEAVY RAINFALL IN SCOTLAND.**—Last week (page 29) we published monthly accounts of rain at Curraghmore, Ireland, the year's total amounting to 42.59 inches. A correspondent now sends us the following records:—"The rainfall for 1898 recorded at North Craig Reservoir, parish of Kilmarnock, was in January 3.15 inches; February, 4.10; March, 1.85; April, 2.05; May, 1.95; June, 2.70; July, 1.65; August, 5.00; September, 5.00; October, 4.05; November, 5.95; December, 7.75. Total, 46.10. Average yearly fall, 41.94 inches."

— **SHIRLEY GARDENERS' ASSOCIATION.**—The monthly meeting of above Society was held at the Parish Room, Shirley, Southampton, under the auspices of the Technical Education Committee, Southampton County Council. Mr. W. F. G. Spranger, C.C., presided, and a good number of the members were present. The lecture, which was entitled "The Effects of Electricity on Plants," was given by R. W. Stewart, Esq., D.Sc., London, Principal of Hartley College, Southampton, was illustrated by diagrams, electric apparatus, and lantern slides, and was both interesting and instructive.

— **A USEFUL DESK PAD.**—We have just had forwarded to us one of the most useful desk pads we have seen. It is from the great sundriesmen, Messrs. Wood & Sons, Ltd., Wood Green. For gardeners it should be extremely valuable, more particularly perhaps the diary given on the left hand side, and in which each day is allotted goodly space. Important memoranda made therein could scarcely be lost, and certainly would be handy for reference. The pages are interleaved with blotting paper, and that means a saving of valuable time when work presses. The central portion is devoted to the customary blotting sheets, while on the right is the pencil in its loop of elastic, pockets for paper and envelopes, and a tablet for notes of moment. The left and right hand sides close over the central pad when it is not in use.

— **HORTICULTURAL CLUB.**—The usual monthly dinner and conversation took place on Tuesday last. The chair was occupied by Mr. Harry J. Veitch, and there were present besides the Rev. W. Wilks, the Rev. J. H. Pemberton, Messrs. Charles Shea, George Monro, James H. Veitch, G. Bunyard, C. T. Druery, and others. The discussion was opened by Mr. Chas. E. Shea with an interesting paper, entitled "A Chat About Chrysanthemums." Many points of much value were brought forward, and there seemed to be an unanimous revolt against the race for size which now marks the Chrysanthemum. Most of the members took part in the discussion which followed over the paper, and many interesting statements were made. A hearty vote of thanks was accorded to Mr. Shea. It was announced by the Secretary that the annual meeting would be held on February 14th, when the chair would be taken by Sir John Llewelyn, Bart., M.P., the Chairman of the Club, and ladies would be specially invited to attend.

— **MAKING PEACH BORDERS.**—Certainly I have every reason to be satisfied with the results of my request for criticism on a proposed compost for a Peach border. That the compost has been unanimously condemned as too rich and soft I fully realise, and trust that young gardeners who may some day have to perform the work of making stone fruit as well as Vine borders, have noted the criticisms, and will benefit by them. There can be no doubt but that the evils which have come to both Vines and stone fruits have largely arisen from over-made, too enriched soft borders, which have bred in the Vines and trees all sorts of diseases. I have been specially pleased to have drawn from his well-earned retirement that fine old gardener, Mr. David Thomson, whose long life experience in these matters should make him a master to whom young men should listen with all due respect. Youth is often in a hurry, but the old greyheads of the profession know from life-long experience that too great haste in culture too often leads to failure. Gardening is of so progressive a character that even the oldest have never done learning. I should not like to be always suggesting subjects for criticism, as some may be more or less empirical, but there does constantly occur to readers of the *Journal of Horticulture* topics of exceeding practical interest, and the starting of one of these topics now and then with such results as have followed my little venture, cannot have other than very practical value. Being of a practical turn of mind I prefer practical writing, hence I thought what so far has been done is well worthy of more complete following.—A. D.

— **WHAT IS THE "RECORD" CROP FOR AN APPLE TREE?**—In an account of a remarkable old orchard in the United States, given in an American paper, the writer states that the late owner often picked twenty barrels of greenings from one tree. Now twenty barrels would be nearly 60 bushels, and such a yield is almost incredible. Are there any records of great yields of Apples per tree in this country? Perhaps you or some of your readers may have memoranda of wonderful yields.—**INQUIRER.** [We have assisted to gather 80 pecks of fruit from a standard Apple tree, and were informed that its maximum crop amounted to 120 pecks. This is only half the above "record." Perhaps some of our readers may be cognisant of heavy yields by individual trees.]

— **ISLE OF WIGHT.**—The annual meeting of the Isle of Wight Horticultural Improvement Association was held at Newport Guildhall on Saturday last. Dr. J. Groves, B.A., J.P., presided over a large attendance of members from all parts of the Island. After the confirmation of the minutes of the last annual meeting the report for 1898 was adopted, on the proposition of the Chairman, seconded by Mr. R. F. Eldridge, Vice-Chairman of the County Council and Chairman of the Technical Education Committee. Then followed the election of officers for the ensuing year, after which a social entertainment took place at Warburton's Hotel. Mr. A. Guy staged a collection of well-grown Cyclamen, for which he received a vote of thanks.

— **HEAT AT THE ANTIPODES.**—The subjoined figures from a daily contemporary will probably assist some readers to become reconciled to the weather and its vagaries to which we are being subjected. An abnormal heat wave passed over the Colony of Victoria, Australia, last month, and on the 5th the "record" was nearly beaten. The maximum in Melbourne was 109.4° in the shade at 3.45 P.M., and 158.3° in the sun, while Mildura registered 110° and Swan Hill 112° in the shade. The day began in Melbourne with a shade temperature of 96° at nine o'clock in the morning, at 2 P.M. the reading was 109°, and by a quarter to four, with a shade temperature of 109.4°, all hot December days since 1876 were eclipsed. In December, 1876, the record in one day was 110.7°. Last December twelvemonth the highest reached was 107.3°, and throughout all last summer, trying as it was, the hottest day was January 11th, 1898—109.2°.

— **HESSLE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.**—A meeting of the above Society was held on Tuesday, January 10th, 1899, Mr. G. Wilson, Swanland Manor, in the chair. Mr. J. Barker, gardener to W. P. Burkinshaw, Esq., Hessle, read a paper, entitled "Orchids for Beginners." The essayist dealt with those Orchids which are most suitable for beginners, giving the houses and the temperatures suitable for the different species. The essayist also exhibited a group of Orchids of his own cultivation, which comprised *Cymbidium Traceyanum*, *Odontoglossum crispum*, and *Cypripedium insigne*, *Niobe superhum*, *Leeanum giganteum*, *Euryades*, and *Pitcherianum*, Williams' variety. There was also a decorative competition for under gardeners for a lady's spray, and a gentleman's buttonhole bouquet. They had to be made in the room before the meeting commenced. The Judges, Mr. Wilkinson, Elloughton, and Mr. C. Lawton, Welton, awarded the prizes as follows: First, Mr. M. Skinner, Bishop Burton Hall, Beverley; second, Mr. Flowers, Tranby Croft; and third, Mr. Donoghue, Tranby Croft. The exhibits were highly interesting, and showed considerable artistic skill. The usual votes of thanks to the essayist and Chairman brought a highly enjoyable and instructive meeting to a close.—J. T. B., Hessle.

— **THE METROPOLITAN PUBLIC GARDENS ASSOCIATION.**—At a recent meeting, under the chairmanship of the Earl of Meath, the sixteenth annual report was read and approved. It stated that during the past year the Association had laid out six new grounds, furnished gymnastic apparatus for another ground, provided trees and seats in sixteen localities, and by means of special gifts from its members erected nine drinking fountains in public gardens and playgrounds, and also given assistance in the acquisition or improvement of a number of other grounds, and in opposing Bills in Parliament which affected public open spaces. It was agreed to approach the Corporation of the City of London with regard to the maintenance of City churchyards, to commence the laying out of Portland Place enclosure in the New Kent Road, to communicate with the London County Council respecting the management of Hampstead Heath, and to make further inquiries about the proposed recreation ground at Finchley and the suggested acquisition of a portion of Wimbledon Park, which is for sale, near Wimbledon Common. Among the subjects discussed at the meeting were the local control of small open spaces, the scheme of the future management of the Physic Garden, Chelsea, and the laying out of Brunswick and Leyton Squares, Camberwell.

ANGRÆCUM VEITCHI.

WHEN the several Committees of the Royal Horticultural Society met at the Drill Hall on the 10th inst. *Angræcum Veitchi* certainly attracted more attention than any other individual plant in the hall. As may be gathered from the name, it was shown by Messrs. J. Veitch and Sons, Chelsea, and it is a hybrid resulting from a cross between *A. sesquipedale* and *superbum* (*eburneum*), of which the former was the seed-bearing parent. The firm's clever hybridist, Mr. J. Seden, had in view the desirability of an increased number of flowers on a spike, and this object will in all probability be achieved when the plant gains in strength. The habit of the plant is quite intermediate between the two parents. The growth is more robust than in *A. sesquipedale*, and the very thick leaves are wider apart on the stem. The flowers are quite as large, if not rather larger, than those of that species. The clear satiny white lip of the hybrid is quite distinct from the seed parent, but partakes more of the character of *A. eburneum* in being wide and open. The spur or tail of *A. Veitchi* is much shorter than in *A. sesquipedale*. The plant staged, and from which our illustration (fig. 10) was taken, was eleven years old, and received a first-class certificate from the Orchid Committee, Mr. J. Seden, V.M.H., receiving at the hands of that body a silver Flora medal for this the first hybrid *Angræcum*.

CATTLEYA DOLOSA.

I FIND no difficulty in flowering *C. dolosa* under the treatment given below. While growing I keep it suspended near the glass at the warmer end of the Cattleya house, affording copious supplies of water by dipping the basket once or twice a day. When the pseudobulbs are matured it is removed to the cooler end of the house and given a rest for a few weeks, but water is never entirely withheld. It is a species that dislikes undue disturbance of the roots; therefore when rebasketing it is absolutely necessary that ample drainage be given, taking care to keep the plant well elevated, and encourage the roots to ramble outside and cling as much as possible to the basket. Peat fibre, with the addition of charcoal nobs, should be employed in the making up, finishing off with a surfacing of sphagnum moss.—G. HAGON, *Fowley*.

RESTREPIAS.

THESE are wonderfully constructed and delicately beautiful little Orchids, worthy of a place in all collections. The elegant blossoms, borne on slender stems, are so delicate and many-coloured that any description falls short of the real thing, and gives but a very poor idea of what they are really like. From Upper Mexico to Southern Brazil these pretty plants are more or less thickly scattered upon the high mountain ranges, and thence collectors have, with much difficulty, sent them from time to time. The genus was dedicated to one of the earliest travellers in these regions, Mr. J. Restrep, by Humboldt, who discovered the first and most generally cultivated *M. antennifera*.

The culture naturally comes very near that of the *Masdevallias*, to which the *Restrepias* are closely allied. This is a cool régime, with ample atmospheric moisture the whole year round, plenty of light during winter, and a constant shade during the summer months. As may be supposed from their habitat, air is as essential to their well-being as moisture, and as long as possible a chink of air may be left on the top of the house wherein they are grown, and a little below all the year round, keeping up the winter temperature to a minimum of 50°, and not allowing the heat in summer to rise much higher than 60° if it can be avoided. Under these conditions they will enjoy life and flower abundantly.

ODONTOGLOSSUM PULCHELLUM.

This pretty species is again in flower, and every year it seems to gain in favour. Little wonder either, for it is one of those charming little kinds that look extremely well, whether on the plant or off, and is moreover one of the easiest in the genus to cultivate. The flowers occur on erect scapes from the side of the bright apple-green pseudobulbs, and have a fine appearance against the narrow sedge-like foliage. The flowers are individually small, but pure glistening white, with a yellow centre to the lip, and they bear a strange resemblance to a small inverted raceme of *O. citrosum*.

It was discovered by Mr. G. Ure Skinner, who sent home to Mr. Bateman so many fine Orchids early in the present century from Guatemala and the neighbourhood. It is plentiful enough now in collections, though for many years after its introduction it was very

rare. There are no coloured varieties known, or at least in general cultivation, but there is considerable variation in the size of the flowers. No Orchid is easier to grow in a house such as suits *O. grande* and similar kinds, and it is one of the best for a cool fernery. Repotting should take place as seldom as possible, once in three years being quite often enough. Fairly wide pots, a thoroughly clear drainage, and a thin compost, consisting of peat and sphagnum moss, suit it well, and water is necessary all the year round.—H. R. R.

SOIL ANALYSES.

WHEN I originally invited discussion on page 455 (last vol.) by suggesting certain information as to soil and site, along with results of crops only, as usually given in lieu of such details, I suggested that such limited statements were no lessons for readers, and that I hoped for the said details so that others (myself included) might do likewise under similar conditions, thus characterising myself distinctly as a learner, as I shall be all my life, concluding it with the paradox that the more I know the less I know, as each step in learning will only display before me a fan-like extension of the unknown. With this inquisitiveness of mind I can conscientiously declare life too short, however long it may be in years.

From these premises, partly stated originally, I should have thought my assertion that I am "no chemist" was almost superfluous. But I should like to affirm myself very much alive to common sense views that are the half-way house between exact science and rule-of-thumb in regard to production from the soil, and concerning which some very good hands at this industry would probably share my views as to its being a very fair basis to occupy when we are "no chemists."

I do not for one moment contend that direct experiment is not very valuable. On the contrary, I have said more than once it should concur with analysis of the soil. If analysis precedes, and the lime question is thus solved, the direct experiments following will occupy less time than by ignoring analysis and experimenting some years, and having to acknowledge ourselves beaten in some cases by the very insufficiency of lime; others, if lime be present, will be more fortunate. To say that the presence of lime can be demonstrated by twopence spent in chemicals is quite correct, but the operation does not register its proportion, and hence the 10s. expense for the mechanical part of the process is highly instructive, as it simultaneously informs us equally well about proportions of humus, clay, and sand, and every enterprising gardener ought to look to it.

In spite of an "English Gardener," whom I suppose I am directed by himself to identify with "Gardener, *England*," on page 481, last vol., I make bold to assert that I had my own orchard, probably at an age when he was in charge of none, as I was only seven years old when I planted it with self-discovered seedlings of Apples, Pears, Plums and Cherries, from pure love of the subject from those early days that has never since deserted me. Yet perhaps he will forgive my faith in our getting on very well together, as nothing attracts me more than the capacity of taking trouble; and that he has done in having ten analyses made from a soil not homogeneous, and thus obviously unfavourable for my purposes, as he thus found completely differing results between them all. But he still omits to inform me of the proportions of lime he found, and yet the main factor of my entire argument is the presence of lime, a very broad basis admittedly, which does not soar beyond common sense capacity.

Nobody will dispute the obvious truth of the greatest successes in cultivation having been derived from direct experiment, because they extend back some generations, whereas analysis so applied is a short cut in modern ways that is destined to economise direct experiments, and which has yet many sceptics to contend against whose successors may take opposite views, although soil not homogeneous will ever continue to require exceptional treatment. An "English Gardener" only does the right thing in such restive conditions of soil as he has to contend with, in preferring a gardener's instinct to direct the management. But want of faith in analysis is beyond this cavil, and the pessimism expressed is simply misdirected energy.

My reference to Mr. Cousins' treatise was quite to the point and very brief, concerning absolutely only the bare fact of his deprecating proprietary manures. If "English Gardener" obtained the book and looked for a variety of information he was unable to obtain he is not justified in blaming me. Being "no chemist," I am able to learn a good deal from it. I advise my critic to refresh his memory as to the last paragraph of mine on page 481 concerning the value of analysis of the soil as judged by competent City chemists named and their faith, quoted as expressed by them in the "Standard" recently.

Nor had I mentioned or directed "English Gardener's" attention to plant ash analysis, having heard such contradictory value attached to it, including Dr. Hall's own words, as listened to by me in his lecture at the Drill Hall, and Mr. Cousins' in his Primer. (That both these gentlemen are members of the Kentish College at Wye may be

unknown to "English Gardener.") I am thus unconscious of the motive of this argument being brought into battle as if it were making a point against me. My common sense told me to keep aloof when doctors differ, and to prophesy only when I know, as I do know about lime, which those who fail to analyse soil do not. Could "English Gardener's" life be lived over again, with a little previous knowledge, and having to deal with homogeneous soil, he might be brought to bless analysis in all its forms, even including plant ash, which is held in great esteem in some foreign lands rich in faith in analytical science.

As to "Wanderer," his friend Jones may have become greyhaired since the greater part of a generation in the protracted effort to learn

BARK PRUNING AND LIFTING OLD PEAR TREES.

I WAS greatly interested on reading the profitable results obtained from Mr. Edward Luckhurst's practical advice to ring or bark-prune the rampant growing fruitless Pear trees. The results proved to have been more profitable than could have been reasonably anticipated from such a simple operation, described on page 470, December 22nd. In the following week's issue "W. R.," on page 497, quotes an instance where bark-pruning was perfectly successful. The Editor gives further evidence of what has been done by bark-pruning or ringing, with little cost of labour. I shall be glad to learn from practical correspondents

FIG. 10.—ANGRÆCUM VEITCHI.

the lessons acquired from direct experiment he abides by, unless he had a kind preceptor in younger days, especially if on the identical area. Nor do I say that deep digging and trenching is not worth more than promiscuous manuring. Make the best of any soil workable at all, I have said more than once, but do not despise the aid of science, although it is manifest that the only feasible effect producible by analysis is to enable higher class produce than previously obtained to be grown on the most advantageous terms. That extra is equivalent to the difference between a bare living and something to spare.

In reply to the Editor's footnote on page 500 (last vol.) *re* clubbing of Brassicas: of course the discovery of gas lime as an antidote against that evil was made by a scientist; I merely quoted the one instance in point only *à propos* of "lime." I am glad of the tribute to science in the closing words on the page cited, and would observe that gardeners must not imagine they are monopolists of editorial endorsements.—H. H. R., *Forest Hill*.

[The Editor believes in the logic of accomplished facts, and that the best results in the production of crops are not achieved by wrong methods, whether these have been based on soil analysis or not. His views generally are condensed in the introduction to Mr. Cousins' Primer, where ordinary soil analysis is not regarded as an essential in cultivation.]

what advantage would be likely to accrue from ringing the stems of Pear trees that have their principal roots down in a hard red hungry clay.

This winter we have lifted and root-pruned seven horizontally trained Pear trees. Five out of the seven have been planted about thirty years, the other two not such a long time by ten or twelve years. The varieties being good ones—viz., two Marie Louise, with one each of Winter Nelis, Doyenné du Comice, Easter Beurré, Hacon's Incomparable, and Williams' Bon Chrétien—I wished to improve them. The trees produced plenty of wood, but the foliage was of a yellowish green, and very thin in texture. The trees averaged about 20 feet run of wall 12 feet high. For the last six years the seven trees have not produced two stones of fruit in one season. They are planted on east and west aspects.

It will be easy to understand that since the trees were planted, thirty years ago, that the borders have been raised considerably through adding various manurial agents. We commenced about 8 feet from each stem to dig out the first trench, and gradually worked away the soil. Very few roots were nearer the surface than 2 feet, except a few small ones recently made through top dressing, and liquid manure, which was given three times a year. Two roots growing from the stem, and as near the surface soil as it was possible to select, were

left to each tree; all the other large roots, being in the clay, were severed. Each tree was then lifted or raised up about 12 inches, in some cases more, the roots being well packed up with fresh soil (after digging out the clay) about three to five barrowfuls to each tree. The best of the old soil was returned, well mixing with it a quantity of basic slag. Some of the tree stems, from the collar upwards, were buried from 12 to 15 inches with soil. After the roots were laid near the surface and covered with soil, a mulch of half-decayed manure was given 4 inches thick, extending 6 feet from the stems.

Each tree when first planted had a stone slab about 18 inches square placed underneath its roots, or rather, the tree was made to stand upon the slab. The roots had turned over the edge of the slab and gone straight down into the hungry clay, the slabs being fast in the grasp of the roots. I consider that placing a slab underneath a tree when planting to be useless; it sounds very well on paper, but benefit to the tree is *nil*. What effect the above operations will have on the old trees time will show. I have operated on old fruit trees in a similar manner years ago, and in two years after the operation they bore respectable crops of good flavoured fruit.

Some of your readers may perhaps come to the conclusion that I have been wasting time in root-pruning and lifting those seven trees. What led me to take action was the condition of a Marie Louise Pear of the same age. It had been planted close to the doorway of one of the main paths. This path being much lower than the borders half of the roots were underneath it, and the neck or collar of the tree was not covered with soil, similar to those that have been lifted. Through making holes in the gravel paths with a crowbar, then giving 70 or 80 gallons of liquid manure about three times a year, 3 to 4 stones of splendid russety fruits have been produced during the last three years, or more than the whole of the seven trees just lifted produced.

How trees can live in the hard clay is a mystery to me. You may give 100 gallons of liquid manure to each tree, but by the time it reached the roots it would be little more than clear water, having been filtered while passing through the 2 or 3 feet of soil from the surface down to the roots. Hacon's Incomparable had one root nearly as thick as the stem and went straight down into the clay. Result—abundance of long weak shoots, with foliage of a yellowish hue. Tree produced eight to twenty fruits per year, never fit to eat. They remained (not as good as a Turnip) in the fruit room, quite hard. All at once the fruit would become rotten; there has never been a fruit fit to eat for the last six years that I have known the tree (aspect west). Easter Beurré, on the other side of the wall (east aspect) produced about 10 to 12 lbs. of fruit each year, about 1 lb. of the fruit useable, the remainder covered with black spots and much cracked. The principal roots being deep down in the red clay, what I should like to know is this—would ringing have improved those trees? Cordon Pears on the same walls give good fruit.—GEORGE PICKER.

[We should doubt the efficacy of ringing under the circumstances, but are open to conviction by "W. R." or others who have reason to think differently. If the branches of the trees are fully too close together the removal of every other to near the stem might lead to the issue of young branches while lessening the strain on the much-reduced roots; and if the spurs on those remaining are closely set reducing them to a foot apart or thereabouts would be further conducive to healthy growth.]

ROYAL HORTICULTURAL SOCIETY.

JANUARY 10TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair): Mr. Veitch, Mr. Bennett-Poë, Dr. Müller, Dr. Russell, Rev. W. Wilks, Prof. Church, Mr. Michael, and Rev. G. Henslow, Hon. Sec.

Bigena Orchid.—Mr. Veitch exhibited a flowering plant of an *Epicattleya* (Mrs. Jas. O'Brien), *Epidendrum* × *O'Brianum*, the latter being *E. evectum* × *E. radicans*. The male parent was *Cattleya Bowringianum*. It has been stated that in these *bigenas* the result generally resembled the female parent almost entirely, but in this case there was a decided inclination towards *Cattleya* in the form of the lip and foliage.

Mildness of the Season.—Mr. Wilks brought a spray of Oak leaves, still partially green, and mentioned that Blackberries had been lately gathered ripe—an unusual occurrence in early January.

Thuja gigantea (plicata) barked.—Dr. Masters showed a stem which had been nearly stripped of its bark, exposing the central axis as an almost cylindrical rod. The young wood had made renewed efforts to surround the latter, which appeared to be dead. It was received from Mr. Croucher, of Auchstertyre, near Crieff.

—PEAR PRINCESS.—When at the Chrysanthemum Show in St. George's Hall, Liverpool, in November last I tested the flavour of this Pear. In appearance it much resembles Louise Bonne de Jersey. The flavour is first-class, being exceptionally juicy and sweet. It is said to grow vigorously and bear freely on the Quince stock.—E. M.

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening last the Executive Committee of this Society held a meeting at Carr's Restaurant, Strand, when Mr. T. W. Sanders took the chair. Minutes and routine correspondence having been disposed of, the report and circular of the Classification Committee, intended to draw the attention of affiliated societies to the question of too-much-alike varieties, were submitted for consideration. The election of Judges for the 1899 shows next occupied attention with the following results:—October Show, Messrs. G. Langdon and J. McHattie; November Show (plants), Messrs. D. Donald and Reeve; incurred blooms, Messrs. Geo. Gordon and J. W. Moorman; Japanese, Messrs. E. Beckett, T. Bevan, E. Molyneux, and R. Parker; decorations, Messrs. J. Hudson and H. J. Cutbush; fruit, Messrs. G. Reynolds and J. Smith of Mentmore; vegetables, Messrs. H. C. Prinsep, W. Fyfe, J. Willard, and G. Maycock; at the December Show, Messrs. W. Mease and P. Waterer. The Judges of miscellaneous exhibits at all the shows are Messrs. Gleeson, Outram, and Witty.

The Secretary next read the draft annual report, to be submitted at the general meeting. In this the work of the past twelve months was reviewed, and satisfaction expressed. The draft financial statement and balance sheet was also submitted, and both were recommended to be laid before the annual meeting in the form presented. There was much discussion concerning alterations of rules, the voting of representatives of affiliated societies, and other formal matter. Some new members were elected, and the meeting closed.

WELLS' CHRYSANTHEMUM CALENDAR.

CHRYSANTHEMUMISTS seem ever to be on the search for novelties, literary and otherwise, and we cannot say there is any particular lack of either. This calendar of what should be done under the different months in growing Chrysanthemums is no microscopic or even waist-coat pocket affair, and, if affixed to the wall of potting-shed or office, will be distinctly visible to the naked eye. It is a sheet about 3 feet long by nearly 2 feet wide, embellished with photographic illustrations of Australian and other novelties, with the letterpress bold and clear. Mr. Wells evidently attaches importance to "size," both in blooms and bills, and both are of good quality in this latest from the press of Redhill.

FEEDING CHRYSANTHEMUMS.

I READ with much interest "T. C.'s" contribution *re* chemical constituents of the Chrysanthemum plant, and I have often thought it would be of great service if one of your contributors would give an article or articles dealing with the scientific treatment of the plant with regard to feeding, from the stage of the young plant onwards. By feeding, of course I mean anything added to the loam, be it only leaf mould—not only the liquid feeding of August onwards.

It seems to me a lazy and wrong principle to be satisfied to apply either dry or in solution any particular mixture of artificial manures without the knowledge of what they are composed. I have no doubt that most of them are very good, but there is no guarantee of their composition, or that they are invariably alike, so that you may easily be using at a given moment something which is absolutely useless to you for the particular plant and stage of growth in hand.

As it is a rather slack season now, would it not be a good opportunity to publish a contribution on the subject from some reliable scientific horticulturist, and also from experienced growers, which would tell us in plain language exactly what the Chrysanthemum should have during its life to attain the highest possible result, not "so much of Smith's, Brown's, or Robinson's manure for all kinds of plants," but specifying the amount and proportion of phosphates, potash, lime, nitrogen, or whatever may be needed; the most economical form in which each may be supplied to the plant, and the intervals at which each (or several mixed) should be supplied.

I have no doubt such information would be greatly appreciated by the large number of your readers, amateur and otherwise, who make their gardening a real pleasure and study, if you can see your way to adopt my suggestion.

I must remark in closing that I was rather surprised to hear of a successful grower and exhibitor using nitrate of soda and sulphate of ammonia so often as stated, to even the strongest growers, which is, I believe, so contrary to the accepted practice. It would be useful to hear from some of our best known cultivators on this point.—J. G. MILLS.

CHRYSANTHEMUM TRADERS.

I AM not surprised that under the pressure of my recent tread some of the Chrysanthemum traders have turned. I wanted them to do so, because it enables me to say again that if there are proceedings in relation to awards of medals or other things made by the N.C.S. to which traders object, their proper course is to wash their hands of such a body, or failing that, to bring forward their complaints and objections at committee or members' meetings, and not intrude such objectionable topics into trade lists. Who of Mr. Wells' customers—and I hope he has thousands, for I heartily wish him well—cares a straw for the N.C.S. or its doings? If it wished to take a suicidal course by disgusting persons, and the members sit idly by and see it so drifting, that is their business; but it does not concern the great Chrysanthemum growing public one atom. I fear it is not only at the Aquarium that traders exhibit and obtain medals for plants or flowers, ostensibly their own, but which they did not grow. If the practice is objected to by members of the N.C.S., let them get a condition inserted that any person, trader or otherwise, exhibiting products in his name which he has not grown, at the N.C.S. shows he expelled from membership. That is the way to deal with what they may deem a grave impropriety, and far preferable to dragging such subjects into catalogues.—A. D.

YOUR correspondent, "A. D." (page 13), in dealing with this subject, seems to have got a little out of his depth. Has he any idea of the amount of expense necessary to maintain a collection of Chrysanthemums, either as a trader or private grower? I think not.

Take the example of the private grower first. Many gardeners look to the prize money to purchase new varieties, without which they have little chance of winning prizes, or even showing creditably. Does "A. D." know of the many hours an exhibitor has to work, for which he receives nothing? Love of the flower he must have, but a little of the gold that he so freely speaks of is necessary to pay the numerous expenses the competitor has to meet. In very few gardens is everything connected with exhibiting charged to the owner. Perhaps our friend has a competency, and can afford to work for nothing. If so, that is no reason why gardeners, who are generally poor men, can afford to exhibit for nothing, and pay their own expenses.

Now, as traders, all firms dealing in this particular line should have equal opportunities. We are aware that gold medals in goodly number have been awarded to exhibits, some part of which have not been grown by the exhibitor, and consequently why those who have shown what they have grown are not entitled to tell their patrons so in catalogues I cannot understand. So long as medals are given, they should go to worthy exhibits without favour. In advertising its goods, a celebrated firm shows a medal, said to have been awarded by the N.C.S. for the most complete collection in the kingdom. Did the Society ever award such a medal?—FAIRPLAY.

[We cannot imagine a N.C.S. judge risking his reputation by favouring any particular exhibitor, and if such an outrage occurred the Committee would surely purge itself of such an unworthy member. More than one or two Chrysanthemum purveyors conscientiously believe they possess the best collections in the kingdom, and if so they naturally advertise what they believe to be the fact. One thing is certain, they would not occupy commanding positions in the Chrysanthemum world if they did not advertise in some way, but only grumbled. If the classes of the N.C.S., some of which have been of undoubtedly wide scope, require alteration, pressure should be brought to bear on the Committee to alter them, but competitors are not open to reproach who act within the stipulations, and if they did not so act they would be open to disqualification.]

— PLANTING OF FRUIT TREES.—With respect to the subject matter of the paragraph taken from the "Irish Farmers' Gazette," and published on page 9 of the Journal, as to the proper depth to plant fruit trees, I can but ask whether, when budding of the stock is properly done, there is any "scar" to hide, or even to be more liable to suffer injury than other portions of the stem? Is not that nonsense? But has anyone in experience ever found the scion, if budded on the Paradise stock low down, to later, if planted below the bud union, throw out roots? I have never found such to be the case, and I think it is purely imaginary. To plant deep with such anticipation would be doubly wrong, as not only is such scion-rooting most improbable, but the variety is worked on the dwarfing stock for special reasons, and to induce the formation of scion roots would be to destroy the object aimed at in budding, and even to render the proper stock roots largely useless and inoperative. Without doubt the closer relatively that roots can be kept near the surface the better. Naturally they will seek to descend into the earth in just the same way that branches seek to ascend; but whilst in the latter case it is often our aim in the production of fruit to endeavour to make these grow rather horizontally than vertically, so have we in the case of roots to largely endeavour to counteract Nature's downward attractive force by seeking to keep them horizontally growing also; not only because the surface soil is being most aerated the sweetest, but is also the most convenient for feeding with manures, and thus supplying fruit tree needs.—A. D.

JOTTINGS.

WE sometimes talk of the busy season, but I wonder if any of us can call to mind a really good gardener who is not "busy" at all times. True there are seasons when work presses upon us in almost overwhelming force, when our energies and aptitude for management are taxed to their utmost limit; but the real secret of success in going through these ordeals is in being prepared for them by making a good start with the new year. To keep any establishment going satisfactorily little improvements have to be continually made, as each season should teach us some lessons in economic management or cultural advances. Failures of some kind or other will always occur under the best of management, and to know the cause of such is the first step toward turning failure into success. How often may we trace failures to the simple fact of making too late a start, and then pushing plants or crops, as the case may be, on too fast to make up for lost time. This applies with particular force to bedding plants; unless we have strong sturdy plants with abundance of roots by bedding-out time they can never prove satisfactory, as the season is nearly over before they become strong enough to flower freely. Bearing these things in mind it beloves us to make a special effort during the year which has just begun to have all things in readiness by the appointed time.

Although Pelargoniums are not so freely employed for bedding purposes as formerly, there is still a great demand for them, and to have the plants in good condition by the middle of May next they ought to be taken in hand at once. Those which have been rooted in thumb pots will be ready for a shift into the 3½-inch size, in which they make bedding plants of the best quality. In cases where the cuttings were placed in boxes the strongest should be potted in the same sized pots, and the weaker ones into 3-inch. The overcrowding of bedding plants in winter cannot always be avoided; the result of it usually is that they become spindly. When this happens a good plan is to cut them down to within 2 inches of the soil, insert the cuttings in small pots, and place both the cut down stock and cutting in a warm house; then if former are potted when they have made an inch of young growth, good plants can be produced by bedding-out time.

Good loam, with the addition of a fourth of leaf soil and some sharp sand, forms a suitable compost, provided the loam has been stacked at least a year; but the roots of young softwooded plants do not move freely in newly cut turf, and when they are placed in it a partial failure is often the result. I find that nothing suits them better than old Cucumber or Tomato soil which was removed from the houses last September, and placed in a heap in the open air. If this is now placed under cover, and turned a few times till it becomes fairly dry, no other addition than sharp sand is needed to render it a suitable compost for Pelargoniums, and the majority of bedding plants.

When a good stock of Lobelias is required, the work of propagating should be taken in hand at once. Raising plants from cuttings and by root division is an excellent plan to secure uniformity of growth and colour of flower; but it is not so necessary as formerly, as many notable seed firms now send out seed which produce plants with scarcely 1 per cent. of "rogues" among them. The beautiful compact-growing Emperor William should be grown by all, and of course should be increased by cuttings or division. I like to sow the seed in well-drained boxes, using light sandy soil, which is watered before sowing, the seeds having a slight sprinkling of sharp sand scattered over them. A square of glass is then placed over the box and covered with paper, before being set on a shelf in the propagating house. As the seedlings appear the glass is tilted, and the shading by degrees removed. With such treatment, and due attention given to pricking off before the young plants become crowded, large numbers of strong plants may be quickly raised from a couple of packets of seed, and there is time to still further increase the stock by dividing each clump into two or three later on.

Fuchsias are still extremely popular, being now largely employed in the flower garden, as well as for decorative use in pots. Old plants which have been resting under a stage should now be brought out. Those required principally for supplying cuttings do not need severe pruning; if the points of the shoots are removed young growths push very quickly, and a single plant will supply a great many cuttings. If, however, the plants are required to form compact bushes or shapely pyramids for flowering in 6-inch pots, they should be pruned in closely. Those for forming bushes ought to be cut down to within 3 or 4 inches of the soil, and the main shoot of the pyramids cut back to a point when the wood is strong, the side shoots being pruned to one or two eyes. As soon as young growths appear, shaking-out and repotting should be performed; then, with liberal syringings and a temperature ranging between 60° and 70°, plenty of cuttings will quickly be produced. These, if inserted as soon as ready, will make useful plants in 4-inch pots by bedding-out time, or for flowering in 5-inch pots during the summer months.

Some of the best varieties among the singles are Abundance, Lord Beaconsfield, Arabella Improved, Mr. King, Gertrude Pearson, Resplendent, Charming, Eynsford Gem, Beauty of Trowbridge, Monarch, and King of the Stripes; double, Molesworth, Mrs. E. G. Huggett, Rosalie, Sir Garnet Wolseley, White Phenomenal, and Buffon. Almost any moderately rich soil will grow Fuchsias well, provided they are potted firmly, syringed freely while growth is being made, never allowed to suffer by want of water, and, above all, receive abundance of stimulating food in the form of liquid manure and chemical fertilisers.—H. D.

PERENNIAL BORDER FLOWERS.

(Continued from page 424, last vol.)

ACONITUMS.

TRUE "old fashioned" flowers are the Aconitums, or Monkshoods, as they are popularly called, on account of the form of their blooms, resembling to some degree that of a cow. Wolf's Bane is another popular name, due to the belief that it is particularly obnoxious or destructive to that fierce animal. Nearly all the species are exceedingly poisonous, which partly accounts for the comparative disrepute in which they are held. The Monkshoods are, however, ornamental plants, which if confined to the flower garden proper will deserve the space they occupy by reason of their effective appearance in the borders. When well grown their tall spikes of flowers are very decorative. Where they are objected to because of their poisonous properties the perennial Larkspurs may be substituted.

A. Fischeri is commonly known as A. autumnale. It is a useful species, with panicles of blue-purple blooms, and grows from 3 to 4 feet high, and flowers from July onward. Regarding A. Lycoctonum there is a difference of opinion between various authorities as to the colour of the true plant. It is said by some to be yellow, and by others it is described as blue. The plant known to the writer by this name is a useful and showy flower, with stems 3 to 4 feet or more high, and with clusters of creamy yellow blooms. A. Napellus, the common Monkshood, is well known with its 4 feet high spikes of large blue flowers in summer. One of the showiest of the genus, it is also the most poisonous, and is said to be dangerous to cattle as well as to human beings if eaten. It is evident that this species, at least, should be kept out of the wild or vegetable gardens. The white variety, A. Napellus album, is a handsome plant worth growing in suitable places. A. variegatum is a pretty plant with white flowers edged with blue. It is said to grow from 1 to 6 feet high, but I have never seen it less than 3 feet. Other good Aconitums are A. Anthora, yellow, and A. paniculatum, blue.

The Monkshoods will grow in almost any good garden soil; but their display is increased if it is rich, and not allowed to become too dry. They are remarkably good plants for planting in shade or under trees. They are increased by seeds or division.

ACTÆAS.

Berried plants are often prized in the garden, and one generally finds that those of the Baneberry are appreciated. These berries are, however, poisonous, so that it will be safer to omit the Actæas from gardens where children have free ingress. This fault, notwithstanding, they will be found valuable in shady places. There are only some two species in cultivation in this country. The flowers are of comparatively little effect, and are arranged in racemes. They are white in the plants in cultivation. A. alba flowers in May or June, and has white berries in racemes. The leaves, like those of A. spicata, bear some resemblance to those of the Elder, whence it is said the name Actæa, from aktaia—the Elder. It grows from 1 to 1½ foot high.

A. spicata is the better known species; but the type, which has black berries, is inferior in merit to A. spicata rubra, which has exceedingly bright wax-like red berries in clusters held well above the plant. With the writer this seems to prefer a peaty soil, in which it flowers and bears berries with the utmost freedom, although in the shade of a tree. Both these species come from North America, and may be propagated by seeds or division. Like many berried seeds, it may be some time before the seedlings appear above the surface.

ACTINELLAS.

Two plants under this name are included in the Kew "Hand-list," but of these the better is A. grandiflora, a flower more suitable for the rock garden than the border. It comes from Colorado, and grows from 6 to 9 inches high. The flowers, which are yellow, are about 3 inches across, and much resemble those of many other yellow composites. In damp districts A. grandiflora does not always survive a wet winter. A light dry soil should be prepared for this plant, with ample drainage.

ACTINOMERIS.

Several plants bearing this formidable name are described in works of reference, but are seldom seen. The only one the writer has yet come across is A. squarrosa, which he has seen in two or three gardens, and which is the only species in the Kew Gardens. It is not a plant he cares for, but to those who wish a large collection of yellow composites it may be of interest. The flowers rather resemble those of the Coreopsis, and are in loose panicles at the ends of the winged square stems. It has rather broad lance-shaped leaves, which are well described as coarsely toothed. A. squarrosa grows from 3 to 4 feet high, and may be grown in any ordinary soil in a sunny position. It may be increased by seeds or division.—S. ARNOTT.

(To be continued.)

THE NATIONAL ROSE SOCIETY.

IN reading the report (page 460, last vol.) of the general meeting of the above Society, the proposed alteration of the size of boxes struck me as being rather uncalled for, and more especially if an exhibitor is to be disqualified if his box or boxes are 1 inch too small, or that much more than the proposed alteration. I dare venture to say that eight exhibitors out of ten would have to overhaul his boxes; in fact, I think it would be cheaper to have new ones, as it would cost nearly as much, if not quite, for the alteration. Fancy the expense it would entail! How many members are there who would entertain such an unnecessary sacrifice? In my opinion there are many who would rather withdraw from the Society altogether, especially if it is extended to the classes for twelves, nines, and sixes.

I fail to understand why so sweeping a change is to be made. Matters have appeared to go on without any complaints—in fact, I have heard none whatever—and I think as the present regulation has been satisfactory to the majority for so many years it is unnecessary to have it altered now for the gratification of a few. Further, I think this is a question not to be settled by the Committee only; in a question of pounds, shillings, and pence every member, in my opinion, ought to have a voice in its settlement.—W. M.

BROWNING OR "BRUNURE."

IN reply to "A. B.," I may say that the disease known as browning, or "brunure," appears on the young shoots of Vines, causing the half-grown foliage to contract at the margin and become cup-shaped, then the stem loses its clear substance, assuming a dull appearance with lines of shrinkage. The tips of the shoots become flaccid, effete, and the young wood turns to a dirty black tint. The growth is arrested, and the points of the shoots collapse, often in the case of vigorous Vines to the extent of a foot or more. It is commonest on young Vines, and affects those in the most robust growth, and with the roots healthy. No charge can be made against the management, as it appears under the best cultural conditions.

Close observation clearly indicates that certain nutrients at the command of the Vine are in excess, and possibly deficiency of other counterbalancing elements lead to that condition favourable to the attack and development of parasitic growth. This I find to be a slime fungus, so called, though there is no jelly-like matter, but a dry gangrene, and the organism leading a life almost analogous with the "bacteroids" that aid leguminous plants to "fix" atmospheric nitrogen in their tissues, still forming spores and developing from so-called zoospores, but amœba-like bodies, into plasmodia—a Myxomycetes, to wit Pseudo-commis vitis.

Practical experience has taught me that this particular parasite attacks plants most that are grown in alluvial soils, or those made rich in organic matter by animal or vegetable substances. In the case of Vine borders or composts for Vines there is the soil itself—turf, rich from the decay of vegetation, and in many cases of a vegetable nature. The turf rapidly decomposes when cut, and organic acids are produced abundantly. To counteract these lime rubbish, wood ashes, burnt refuse, and charcoal are mixed with the turf. Some growers employ calcareous loam, especially of the "red" class, including lime in an available form, and a due admixture of iron in the ammoniated state. The late Mr. W. Thomson, in his book on Vines, lays stress on red soils for the Grape Vine, and his brother, Mr. D. Thomson, in last week's *Journal of Horticulture*, recommends calcareous loam for Peach borders. In neither case have I noticed "blacks" in Vine shoots or undue grossness in Peach growths when the loam has not been spoiled by heavy dressings of leaf mould or manure.

To the Vines in question I should apply a dressing of basic slag phosphate—I use the term "phosphate," because some "slags" are worse than useless, from not being properly prepared for fertilising use—at the rate of 1 lb. per square yard, and point this into the soil as deeply as the roots of the Vines will allow, mixing as evenly as possible. Afterwards follow with 4 ozs. of kainit per square yard, and leave this on the surface, for it will disappear fast enough, and if pointed in might, with the lime, form chloride of lime, and injure the young rootlets. This has given the best results with me, sulphates being avoided, especially in the form of superphosphates, for sulphuric acid seems to favour "blacks." If a quickly acting form of potash were used, muriate would be most disastrous to the parasite on account of the chlorine, whilst lime corrects any sourness, and converts, by the agency of micro-organisms, the organic matter into nitrates, especially of lime—the element needed in available form in the soil, to be taken up by the roots into the Vines.—G. ABBEY.

OLDFIELD NURSERIES.

MESSRS. W. CLIBRAN & SON, Altrincham, are to be commended for the interest they afford to visitors in their endeavours to show the varied stock to perfection, and of the unfailing courtesy extended.

Though Chrysanthemums are grown principally as cut flowers to supply the demand for wreaths and other floral designs, yet the firm is alive to the fact that to meet the requirements of all, large blooms are indispensable, and Mr. Fletcher, the grower, has everything old and new, and the 6000 pots of various varieties make a wonderful display. The firm is introducing some seedlings of both Japanese and incurved that should become very popular. At the time of my visit single varieties were charming, and a greater future for these may be safely predicted. The shades of colour in the newer seedlings are really remarkable, and beyond the possibility of description here. The houses cover some 6 acres, all finely stocked with healthy produce, pot Roses well ripened forming a great feature. The Cyclamen houses arrest attention, and show that the firm is in the forefront in every way.

The deciduous trees had entered their winter sleep, but the falling leaves of the Ampelopsis and Maples gave tokens of the rich autumnal colouring that had been. Robust health is always attractive, and the vigour of the Ivies, shrubs, and Conifers should stimulate every enthusiastic gardener. Ample space is allowed for each tree or shrub to develop naturally, and with careful lifting every two or three years excessive root growth is checked and the development of fibre encouraged. An assortment of some 40,000 Ivies in and out of pots, formed a feature amongst climbing plants, the Irish Ivy being conspicuous; but Emerald Gem, Caenwoodensis, and gracilis were also noticed.

Many thousands of Honeysuckles, Ampelopsis, and Clematis gave evidence of the great demand for these deservedly popular plants. Hollies and hybrid Rhododendrons form specialities in the Oldfield Nurseries—that is, if one may judge from the acres of the latter and the many thousands of grand bush and pyramidal specimens of the former.

About two miles to the east of the Oldfield Nurseries lies the Hale Farm Nursery, chiefly devoted to fruit trees, of which there are about 40 acres. Seedling and transplanted forest trees occupy over 50 acres, whilst Conifers account for a further twenty. As this nursery is on high exposed land without shelter the trees are grown under the severest conditions, and look proportionately vigorous. The fruit trees with their smooth bark, short sturdy joints, and fibrous roots, showed promise of the highest success. We could not help noticing the care and attention exercised in the spraying of fruit and forest trees to prevent the ravages of injurious insects and fungi.

Much ground still remained to be inspected; but the shades of a short December day came quickly, and the train conveyed us from this interesting establishment into the smoke and din of the Manchester streets.—A VISITOR.

WALDSTEINIA TRIFOLIA.

THIS, "J. W. W.," is by no means a new plant, having been introduced to this country many years ago, though it is by no means so widely known as it ought to be. For planting, either in exposed places on the rockery, or in the deep shade of woods, it will be found very useful, as it grows in both equally well. It is also a very desirable plant for a place near the front of a mixed flower border. It is dwarf in habit, seldom attaining more than a foot in height. The loose corymbs of Buttercup-cup-like flowers are very attractive, and are developed profusely. The leaves, which are divided into three leaflets, are borne on creeping chiefly underground stems; they are slightly hairy and serrated at the margins.

THE MICROSCOPE IN THE GARDEN.

IT is because I have so seldom met with a gardener who possesses a microscope, that I am prompted to write a few words on its value. It has often astonished me too to meet with so few young gardeners who have even looked through a microscope. One can hardly realise it to be true in these progressive days, yet the fact must be admitted. I think if the real worth of a microscope in the hands of a gardener were more generally known, it would soon become as essential as the case of drawing instruments, which some are so proud to possess.

It is not an instrument that can only be brought into practical use at certain seasons of the year, but almost every day. To me there is always something fresh to see, therefore to learn, in connection with plant life, which without the aid of the microscope must have remained unknown. Neither does it compel us to spend a large sum to acquire a knowledge of its manipulation, as do some of our hobbies. For a few shillings a book may be purchased giving details of each part of the microscope, the purpose it fulfils, and the way it is manipulated to the best advantage. So I hope young gardeners will not think that a great outlay is necessary.

We not only gain valuable information by its aid, but a great amount of interest. Especially during the winter months do we realise this, for as gardeners we have not far to seek for objects, either in the insect or vegetable kingdom, and with a little dissecting and slicing we can make objects a wonder to behold without any special preparation, except in the

case of plant sections, when a drop of clear water on the object enables the cell wall to be better seen. We are, then, by the aid of the microscope better able to understand how a plant is constructed; the form the separate organs take; how they are placed so as to contribute a greater amount of strength to the plant; how air is conveyed through the leaves and stem; and how the whole fabric of a plant is built up.

In addition to revealing to us the hidden wonders of plant life, with which all gardeners ought to be familiar, it reveals many secrets of the cause of the diseased portions of plants, which we are all anxious to ascertain if we have a sickly plant. Take, for instance, the Eucharis: it is ten to one if our plants appear to be going wrong there is a very minute insect attacking it somewhere, probably in the bulb, but sometimes in the leafstalk; it is hardly discernible with the naked eye, being so tiny, and somewhat the colour of the bulb, but with a lens numbers of them may be seen feeding. Another of these minute insect pests is the

FIG. 11.—WALDSTEINIA TRIFOLIA.

devastating red spider. Almost invisible to the unaided eye, yet they are endowed with such power of increase, that unless checked they soon spread to an alarming extent. This pest prefers the under surfaces of leaves, where they are less readily detected, thus gaining a firm hold before means are used for their extirpation. And one might go on enumerating microscopic insect pests, so detrimental to plant life and a great annoyance to the gardener. But sufficient (as regards insect pests) for my present purpose have been enumerated.

I will, however, mention one or two fungus pests that are best understood by the aid of the microscope. The ever dreaded mildew, that has played such havoc with some of our choicest Chrysanthemums in the past season, stands prominent in my mind. In reality this is very different to what it looks. To the naked eye it has the appearance of very fine white or rather grey dust distributed over the leaves and stems in patches. But when we peer more closely into it by the aid of the microscope of a moderate power, say of 100 diameters, a great contrast is beheld. Instead of seeing dust, as it before appeared, we see perfect plants, so minute and in such numbers that one is struck with amazement. This fungoid disease is one of the worst pests we have attacking the Chrysanthemum. Smut-blight of Wheat, which farmers are so familiar with in their fields, is a fungus of black colour that often entirely covers the young ears, like a coating of soot, completely destroying the grain. The spores of this fungus are so exceedingly small that nearly 8,000,000 of them would be required to cover a square inch of space. Then, too, they are so light that they sail about in air, and are thus brought into contact with other of their favourite hosts, on which they soon work their spell of mischief. Descriptions of other microscopic pests will serve for a future article.

It has been my sole desire in the present article to give a little idea of the usefulness of the microscope in the garden. If I have created an interest for this branch of study, especially among the rising generation, my desire will be gratified.—ASPIRANT.

THE YOUNG GARDENERS' DOMAIN.

THE CULTURE OF FOLIAGE PLANTS.

(Concluded from page 35.)

CALADIUMS.—These plants should find a place in every collection on account of their sterling qualities for house or conservatory decoration, whilst their value to exhibitors is too well known to need comment. They should be started in March or April in small pots, and when advancing, be placed in whatever sized receptacle circumstances demand. They are moisture-loving plants, and care must be given to keep them well supplied with water at the root and in the atmosphere, when elegant, well-coloured foliage, will repay the cultivator for his care. A similar compost to that mentioned for Crotons will suit Caladiums admirably.

COLEUS AND ACALYPHAS.—To grow these useful plants to perfection abundance of warmth, light, and moisture are essential, but they may be produced with a certain amount of success in different circumstances. Some cultivators have them constantly in strong heat, while others, after starting them in heat, inure them to cooler quarters, and place them in the conservatory or greenhouse. Several of the hardier varieties are utilised with excellent effect in summer bedding.

FERNS.—No foliage plants are more admired than Ferns. To attempt to describe their characteristics here would take up too much space. The chief points in their cultivation are moisture, shade, and not too frequent potting. The usefulness of Ferns is too apparent to need any remarks being passed on the subject; indeed floral work would be at a standstill without their aid.

PALMS.—Both hardy and tender Palms are useful and elegant. I saw a splendid specimen of *Livistona australis* in the gardens of Sir George Meyrick, Bart., Anglesea, planted in the shrubbery, where it stands the variable winters without any serious damage to the foliage. Other kinds may be used for subtropical bedding, affording them a greenhouse temperature during the winter. *Lantana borbonica*, *Seafortia elegans*, *Kentia Belmoreana*, are suitable varieties for these conditions. *Cocos Weddeliana* and *Geonoma gracilis* require a warmer temperature. Too frequent potting is inadvisable with Palms, and a watering with soot water will materially assist to keep the foliage a dark green colour.

REX BEGONIAS.—The curiously shaped, handsomely marbled foliage, of Rex Begonias add colour to many places where other plants will not thrive. They are in no way partial to high culture; in fact they do well on walls, a block of turf being pressed against the roots and secured by wire. As rockwork plants their value is well known.

ASPIDISTRA LURIDA.—This plant is grown in some places in preference to any other, and it certainly deserves all the attention given, as no other will stand the diverse conditions it has at times to undergo. The majority of plants would succumb where it seems to thrive best. The compost should be rather poor, such as ordinary loam, leaf soil, broken sandstone, and sifted lime rubble. After potting, keep the plants in a warm temperature for a short time, until the roots are on the move, when they may be used for the adornment of the conservatory, house, or terrace.

Mention might be made of a host of other foliage plants, but I have confined myself to those in general cultivation.—E. J. B.

EUPHORBIA JACQUINIEFLORA.

As a winter flowering plant for the stove this is worthy of every attention, as it is a free grower and extremely floriferous, while for decorative purposes it is indispensable, the flowers lasting a long time on the plant or in a cut state. The long wreath-like sprays of intense scarlet flowers make the plants very effective when grouped with foliage plants.

They are more easily grown, perhaps, than some of the junior "Domainites" are aware. Cuttings taken in the spring, with a heel of the old wood attached, and inserted in light sandy compost round the sides of a 60-pot, will root readily if placed in a temperature of 70°, kept close and moist, never allowing them to flag. When well rooted put them in suitable pots singly, or two or three as the case may be, using a compost of three parts fibrous loam to one of sandy peat, with a fair amount of silver sand and charcoal. Drain the pots well, and take great care in watering, especially after potting. Afford a day temperature of 80° with sun heat, when a little air must be admitted. Syringe on closing, which should be done early so as to raise the temperature to 85° or more, and keep them well up to the light, shading when necessary. The plants ought to be in their flowering pots by the end of June. When thoroughly established they may receive a weak stimulant twice a week. Admit more air, and reduce the heat and moisture gradually, which will tend to ripen the growth.

After flowering it is the custom with some growers to rest them, as is the case with Poinsettias, but considering that a second crop of flowers can easily be obtained I consider it a loss to do so. When the first blooms are cut we allow them to become somewhat dry, till they show signs of breaking, then with careful watering and frequent syringing they soon make growth, which we encourage with some approved chemical manure. Of course the sprays are not so fine as those first produced, but they are most useful for buttonholes and small glasses for the table.

At the back of our stove, which is a lean-to structure, there remains what originally was a flue, by which the house used to be heated. It is now filled in with old potting soil and planted with various plants, chiefly Ferns and Euphorbias. Some of the latter are several years old, and

were originally in pots, and had after flowering been planted out. The back wall is covered with *Ficus repens*, and to this the growths of *Euphorbia* are loosely tied. The distance from where they are planted to the roof is about 7 feet, and many of the leading growths are in proximity to the glass, thereby receiving plenty of light, which insures flowers of splendid colour. On one plant alone there are forty sprays, not a few measuring from 6 to 9 inches in length.

Beyond the tying and an abundant supply of water at all times, which is needed for the benefit of the Ferns, they have no other attention. When any of the plants die we replace in the spring with those that have previously flowered in pots, and in this way we keep our stove wall gay with one of the best winter flowering plants in cultivation, and that with very little expense.—PARVO.

HARDY FRUIT GARDEN.

Raspberries.—Prune away close to the base the old dead canes of Raspberries and thin out the new canes, leaving the most vigorous, though not more than four or five strong growths to each stool. These, when tied in, may be shortened to the height of the stakes or trellises on which they are trained. The removal of strong weeds with the fork from the soil may follow. The central space between the plants not occupied with fibrous roots ought to be forked up or loosened, if heavy or trodden down hard, but by no means dig in close proximity to the stools, which are plentifully furnished with a mass of fibrous roots close to the surface. Mulching with a layer of rich manure is of the greatest assistance in the culture of Raspberries. The present is a good time to apply a dressing. Liquid manure may also be freely applied to established plants.

Planting and Pruning Young Plants.—New plantations can be formed at this season if strong suckers are procurable, well furnished with fibrous roots. Well worked and liberally enriched soil must be prepared for Raspberry planting. Trenching, or bastard trenching, the ground is the best method of preparation, adding well decayed manure between the spits.

If planting in rows, place the plants a foot apart. In clumps, three plants may be planted in a triangle a foot apart round a central stake 5 feet high. In rows, train the canes to wires stretched between stout uprights of wood or iron fixed firmly at each end.

All newly planted Raspberries should be cut down to within 9 inches of the base, the weaker and insufficiently rooted canes being cut down close to the soil, while those better furnished with roots may be left longest. This close pruning prevents the plants fruiting the first year, but it affords an opportunity for strong, vigorous growth to be made, producing canes which will fruit well the succeeding season. After planting a mulching of light manure might with advantage be spread on the soil between the plants. Good varieties of Raspberries are Superlative, Baumforth's Seedling, Prince of Wales, Carter's Champion, and Red Antwerp.

Pruning and Training Morello Cherries.—These Cherries, grown with free extension on north and other walls, are very productive and profitable if judiciously managed. Plenty of growth is usually made by them, and there is frequently considerable difficulty in laying it all in to the walls or trellises without crowding. The wood is slender in character, and is usually retained and laid in closer than desirable for other wall trees. Fruit is produced best on young shoots of the previous year, and as many of these as possible ought to be reserved, cutting out the old bearing wood when practicable. In some cases old exhausted branches may be cut out entirely and replaced with young wood; indeed the frequent re-arrangement of the whole trees is beneficial. The young bearing shoots must not be laid in closer than 3 or 4 inches. Spur pruning is sometimes wholly or partially adopted, the latter being admissible in treating young shoots for which there is no room, shortening them to form spurs. After the removal of superfluous wood the remainder may be washed with an insecticide, also the walls.

Planting Bush Fruit.—When the ground is in suitable condition Gooseberries and Currants may be planted at the present time. The soil ought to be well prepared by thorough digging and working in some decomposed manure. Plants of two or three years' growth will be found the most suitable. They should not be planted closer than 6 feet either between the plants or rows. Spread out the roots to their fullest extent, shortening long rambling ones back. Cover with good soil distributed from the stem outwards. Do not plant deeply, but make the soil firm about the roots, and finish with a mulch of short light manure. Prune back somewhat closely, so that free growth may be made during the forthcoming season.

Top-Dressing Bush Fruit.—Established bushes of Gooseberries, Red White, and Black Currants will be benefited by a liberal dressing of rich manure over the roots. The most suitable is that to be obtained from the farmyard. This is a mixture of many kinds, rich in plant food elements. It may be placed on the surface, and allowed to remain while the virtues

in the manure are washed down to the roots by rain. Soot is an excellent fertiliser, and may, with great advantage, be dusted freely over Gooseberry and Currant trees as a deterrent against small birds attacking the buds. It also may be applied to the soil over the roots. In short, it protects the buds, cleanses the wood, and fertilises the roots.

Strawberries.—The necessary clearance of weeds, runners, and dead foliage from Strawberry quarters ought to be effected at once if such work has not been done. The soil between the rows must not be disturbed except lightly pointing up the centres. Then spread a good coating of rich manure over the entire space.

Young recently planted Strawberries will not require manuring, but the surface of the soil must be frequently hoed during dry weather for the purpose of keeping down weeds, and promoting the growth of the plants.

FRUIT FORCING.

Cherry House.—Give due attention to watering trees in pots and syringing on fine days, damping occasionally only when the weather is dull. Maintain the night temperature at 40°, 45° to 50° in the daytime by artificial means, ventilating at 50°, and allowing a rise of 10° to 15° from sun heat, with full ventilation, closing at 50°. Scrutinise the trees closely for aphides, and if there be trace of any take measures at once to eradicate them.

Cucumbers.—Maintain a night temperature of 65°, 70° in mild weather and 60° on cold nights, 70° to 75° by day, and 80° to 85° with sun heat. When the external air is mild a little ventilation may be given at 80°, closing before the temperature is reduced below that degree, so as to raise it to 90° to 95°, but if the external air is cold, although the sun shines, it is better to allow the temperature to advance a little beyond the above limits than to admit cold air, which injures the foliage, also causing the fruit to become stunted and to curl at the end. Plants in bearing will require to be examined about twice a week, removing all weakly, superfluous, and exhausted growths, reserving such of the bearing wood as carries young shoots to fill the allotted space, stopping the shoots above, or two joints beyond the show for fruit.

Young plants that have passed the winter so far in fairly good health will make better progress now the days are getting longer and brighter. They are greatly assisted by removing the staminate blossoms, also superfluous pistillate flowers as they appear. Tendrils should also be pinched off. The supply of moisture both at the roots and in the atmosphere must be regulated by circumstances and external conditions. Syringing should not be practised on the foliage, except a light sprinkling in the early part of bright afternoons, damping the floor moderately at about 8 A.M. and 2 P.M. Encourage the roots to spread on the surface of the bed by adding lumpy manure from time to time, with which may be incorporated a little well decomposed cow manure or fresh sweetened horse droppings. When roots are had in this manner the plants may be fed to any extent by sprinkling a mixture of five parts bone superphosphate and two parts powdered nitrate of potash on the surface, at the rate of 2 or 3 ozs. per square yard every fortnight or three weeks, with a light dusting of soot between times.

Keep a keen eye on the plants for their worst enemies—mildew, red spider, and white fly, and paint the hot-water pipes with a cream formed of it and skim milk. The fumes given off will kill white fly and mildew, also red spider. Canker is also unusually prevalent; freshly burned lime, powdered, or slaked with the smallest amount of water necessary, rubbed into the affected parts, will arrest its progress. Aphides are very pernicious, arresting the growth and spoiling the crop. Fumigate several times moderately, and on consecutive evenings, rather than once severely. We find that a dose in the evening and another early the following morning answers the best. Thrips also succumb to fumigation, and mealy bug to vaporisation with nicotine essence. Care must be taken in either case not to give an overdose.

Peaches and Nectarines.—*Earliest Forced Trees.*—Continue to fertilise the blossoms, using a camel's hair brush, feather, or rabbit's tail mounted on a small stick; these are better than shaking the trellis. When the fruit is well set, syringe the trees occasionally in the morning or early part of fine afternoons to assist easting off the remains of the flowers. In bright weather syringing must be practised in the morning and afternoon, but, when dull, have recourse to it in the morning, this and damping the house in the afternoon being sufficient. The water employed must be of the same temperature as that of the house, and the inside border should be duly supplied with it. Disbudding will soon have to be attended to, but it must be done with discretion at this early season, it being better to remove a few shoots daily from a tree than many at a time at distant intervals. The night temperature may now be maintained at 55° to 60° on mild nights, 60° to 65° by day, 5° less as the minimum when the weather is severe and dull, admitting a little at 65°, not allowing an advance over 70° without full ventilation, always excepting a little left at the top of the house constantly.

Second Early Forced Trees.—When the blossoms show colour on the trees started at the new year syringing must cease, but the paths and borders should be damped in the morning and afternoon, except in dull cold weather. Supply water as necessary to keep the border in a thoroughly moist state. Keep a sharp look out for aphides. If there be any fumigate the house on two or three consecutive evenings moderately, which will be sufficient to keep the pests under until the fruit is set. In case of an excess of blossom buds—and they are abundant this season, though many are being cast in some cases, also promising—draw the hand the contrary way of the growth along the under side or back of the

trellis, so as to reduce the number of bloom buds, which will increase the vigour of those left and best situated, therewith tending to a more even and better swelling of the fruit after setting.

Succession Houses.—Push forward the pruning of the trees, dressing the trees with an insecticide, and readjusting them to the trellis, leaving plenty of room in the ligature for the swelling of the branches. The surface of the border may be pointed over with a fork, but not disturbing the roots, the loose soil removed, and fresh loam supplied, sprinkling on it 4 ozs. of basic slag phosphate per square yard. This is particularly valuable on account of the lime it contains, as well as phosphorus, phosphoric acid being slowly yielded to the soil and imbibed by the roots with the water, for Peaches and all stone fruits, especially where the soil is of a rich close nature, full of vegetable matter or humus. In other cases steamed bonemeal, five parts, and double sulphate of potash and magnesia, two parts, mixed, 4 ozs. per square yard, may be applied with advantage. The dressing should be lightly pointed in. In the case of basic slag being used supply also 2 ozs. of the double sulphate of potash and soda per square yard. If the borders are at all dry they should be given a thorough watering. Houses, however, that have movable roof-lights, and these being off, will not require any water, the soil being thoroughly moist. The shoots also are kept in a condition by the air moisture unfavourable to evaporation, so that the trees not only have thorough rest, but the buds are prevented falling.

THE BEE-KEEPER.

ATTENTION TO FLOOR BOARDS.

It is not only in the summer months, but during the short days of winter that the convenience of having loose floor boards is felt by those who are responsible for their management. One has only to examine a hive after it has been exposed to a long spell of dull, wet weather to be convinced that it is beneficial to the bees to have dry floor boards given them when necessary. If it is a fixture there are no means of cleaning them at this season without disturbing the bees.

With movable floor boards the case is very different, as a clean dry floor board may be given at any time without the bees being disturbed in the least. The plan we recommend is to have a few spare boards, and if the hives are all of the same size it saves the bee-keeper much trouble, as all that is necessary is to place one of them by the hive, which may be lifted, and at once placed on the dry board. The same operation can be carried out with the other stocks so long as the dry boards last.

The boards that have been removed are cleaned, dried, and afterwards used again. Several stocks may be done in the course of a few minutes, and it is only reasonable to suppose that colonies of bees treated in this manner will come out stronger and better in the spring than they would had a large amount of *débris* and moisture been allowed to accumulate throughout the winter. A hive may be well made, but more often than otherwise it will be found that moisture accumulates in the corners; this will soon cause the boards to decay, and leave them in an unsatisfactory condition.

EXAMINATION OF STOCKS.

It is advisable at this season when removing the floor boards to make an examination of all the colonies to ascertain if they are short of stores and otherwise in good condition. The bees need not be disturbed in carrying out this operation. We can usually tell if there are ample stores in the hive by lifting up the back of the hive with one hand. If there is any doubt in the matter, carefully remove the outer coverings, and then roll back the quilt so as to expose the outside combs. The bees will usually be found clustered in the middle of the hive, and the combs on each side should contain sealed stores. The outside combs in the hive are always the first to be cleared of their stores in the autumn before cold weather sets in. The natural instinct of the bees has taught them that their food supply must be conveniently near them when they cluster during the dull, cold days of winter.

The plan we have adopted this season with colonies in ordinary frame hives is to remove all the frames outside the cluster that have been cleared of their stores, and replace them with full frames of sealed honey, as, owing to the honeydew, a great quantity of this remained on hand. The sides of the combs nearest the bees were slightly bruised, so that the bees commenced to feed at once. If frames of stores are not available feed with candy as advised in previous notes. If the coverings have become damp they should be dried before being used again. A mild day must be chosen for the necessary examination.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Browning or Brunure in Vines (A. B.).—On page 52 you will find an article from Mr. G. Abbey on browning. We trust the information given therein will assist you in exterminating the enemy.

Books (Bookie).—If you do not possess a book of reference you will find Johnson's "Gardeners' Dictionary" useful. It includes a great amount of information, including much of a practical kind. It can be obtained [from a bookseller for 9s., or post free from the publisher, 12, Mitre Court Chambers, Fleet Street, London, on receipt of 9s. 6d. If you prefer a work on vegetables the most complete is Vilmorin's "Vegetable Garden," with cultural notes by Mr. A. F. Barron. It is published by Mr. John Murray, Albemarle Street. We do not know the price, but it would not much exceed the amount at your disposal. You must now choose for yourself. Your other question shall have attention.

Small Black Ants (Subscriber).—These little creatures are troublesome in pots and care little about water or liquid manure. Place a piece of camphor about the size of a Filbert in half a gallon of boiling water, and when cooled to 110°-115° apply to the infested pots. Some plants will not bear water so hot, therefore use judgment in applying to very tender rooted kinds. Guano water also acts well, while Fir tree oil certainly kills the active animals. We have used this insecticide for ejecting into the haunts of the ants in woodwork and brickwork, and always with excellent effect. Lemon oil also proved efficacious, following the instructions as to dilution. For poisoning see answer to "J. S." in last week's issue of *Journal of Horticulture*, page 33.

Blotches on Leaves of "Greens" (Man of Kent).—The concentric discoloured patches on the leaves are due to the action of a parasitic fungus, closely resembling, but distinct from, the Violet leaf spot fungus, *Peronospora violæ*, which has been prevalent this season. There is no conidial form of the parasite, but the resting spores on the dead tissue are abundant and coincide with *Peronospora parasitica*, Pers., of which one form is peculiar to the Cabbage family. The fungus is an endophyte, and no external application is of any use other than to prevent the spread of the disease. We have found the best preventive dusting with quicklime, using as lightly as possible, and repeating occasionally, the lime being strewn with the hand as near the ground as possible, so as to dash it against the under side of the leaves, and working up and down the rows and on both sides of them. It should be applied when the plants are dry, always lightly and, as before stated, frequently. * will do the land good as well as the plants.

Treatment of Adiantums (Amateur).—Plants from which fronds have been gathered, and only small remains, may be cut over and started again into growth. If placed in a temperature of 55° to 60° they will soon commence pushing up new fronds, when they should be repotted without delay. If the plants need larger pots remove the drainage and any roots that may be crowded about the crooks; the remainder of the ball can be placed in the new pot without disturbance. If the plants are in pots large enough they may be divided by cutting them straight through the middle; the drainage should be removed and the plants potted without disturbing them further. The soil, which should consist of equal portions of good loam and leaf mould, with the addition of sand, must be pressed firmly into the pots. If the plants have been infested with small slugs thoroughly dust the crowns with soot. This will drive them out, and they can be picked off a short time afterwards. Continue this practice until the plants are perfectly free from these pests. A small white caterpillar-like grub occasionally infests Adiantums, and feeds upon the crowns and young fronds just as they form to such an extent that seldom a perfect frond is allowed to develop. These can only be destroyed by thoroughly shaking away from the plants every particle of soil, when they roll out and can be destroyed. The best means of stamping them out is to burn any infested plants. After potting, stand the plants on a moisture-holding base and syringe freely amongst the pots. Very little water will be needed until the plants commence to grow.

Various Plants (J. C. S.).—Peperomias or Pepper Elders belong to the same natural order as the Peppers—namely, Piperaceæ. They are interesting, small-growing, ornamental-leaved plants, suitable for culture in pots: some of the species that are of trailing habit are also well adapted for hanging baskets. These plants must have a stove temperature, but are excellent for temporary decoration indoors, as their stout succulent leaves enable them to stand the change from the stove to the sitting-room. They do well in fibrous peat and loam, with some silver sand. In winter they cannot have too much light, but summer shade from sunshine is requisite. They do not require so much water as many stove plants. *Cypripedium spectabile* has light bright green leaves, furnished with soft downy white hairs, and produces large flowers, the pure white sepals and petals being broadly ovate, and not longer than the lip, whilst the large pouch, which is of a beautiful soft rose colour, is very much inflated. It flowers in June, and may be grown successfully either in a pot or in the open border, thriving well in the shady part of a Rhododendron bed. The plant thrives in a compost of equal parts good peat and friable loam, with a fourth of thoroughly decayed leaf mould, and a sixth of sharp silver sand. It requires to be kept cool and moist in the summer months, and from frost in the winter. Pimeleas are compact, free-growing greenhouse plants that flower when other hardwooded representatives are past. They succeed in firm fibrous peat and silver sand, and should be given a light airy position. You need not hesitate to ask for information at any time on anything in gardening, as we are always pleased to advise according to our ability.

Fertilisers for Onions (E. R. S. J.).—1, We do not consider common salt a necessity for the production of a good crop of Onions where the ground has been liberally dressed with foldyard manure, night soil, and wood ashes, as the last named will supply potash and lime, and the animal manure soda, chlorine, and fluorine. In some cases the salt acts well, counteracting the tendency to produce too much top, especially when the manure dressing is somewhat fresh and the soil of an open nature or light. 2, In the latter case supply the salt as soon as possible, or some time in advance of sowing, disposing evenly on the surface and leaving there. Five cwt. per acre, or 3½ lbs. per rod, is a full dressing, but usually half the quantity is applied. 3, Bonemeal, at least phosphoric acid, is a necessary element for Onions. Superphosphate acts more promptly, and is the article for a heavy soil, using 2½ cwt. per acre, 1½ lb. per rod. It tends to early maturity of crop, which is often backward on heavy land. Limestone soils need less than other land, as they are usually relatively rich in phosphoric acid. 4, Nitrate of soda must be used very cautiously on Onions. If given too soon the plants produce splendid tops and thick-necked bulbs, therefore let them begin to bulb, and then supply 2½ cwt. per acre, 1½ lb. per rod, having it crushed very fine, and using when the plants are dry. Repeat with half the above quantity, when the bulbs are about a quarter grown, and again still lighter when they are half grown. It is better to mix the nitrate with dry earth to insure even distribution and prevent injury to the tops. 5, Bonemeal does not lie long in a limestone soil without being of service. That applied now will give something by the end of April or before, the micro-organisms in the soil seizing the ammonia, or the base with which it combines, and work it up into nitrate of lime. Thus applied in autumn or early in spring it supplies nourishment to the following summer crop, and so on for some years.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The

names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. *Dessert Pears cannot be named in a hard green state.* (S. H.).—1, Knight's Monarch; 2, Easter Beurré; 3, Gloria Mundi; 4, Dutch Mignonne. (J. Smith).—1, Stamford Pippin; 2, Red Winter Calville; 3, Mère de Ménage; 4, Northern Greening; 5, Bramley's Seedling; 6, Dumelow's Seedling (Wellington). (F. D.).—1, Glou Morceau; 2, unknown and worthless; 3, Bess Pool. (G. W.).—1, Cobham; 2, Golden Reinette; 3, Alfriston; 4, Golden Winter Pearmain. (J. H. K.).—The variety is Cox's Orange Pippin, the result no doubt of a graft or bud which had been inserted in the tree. The Apples had either been gathered too soon or kept in too dry a place.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (M. P. N.).—1, Phoenix dactylifera; 2, P. rupicola; 3, Kentia Belmoreana; 4, K. Canburyana; 5, Geonoma gracilis; 6, Cocos Weddeliana. (F. A.).—1, Maranta Veitchi; 2, Phrynium variegatum; 3, Phormium tenax. (H. R. J.).—1, Begonia metallica; 2, B. nitida; 3, B. Ingrami; 4, B. manicata. (R. C. W.).—Freesia refracta alba. The Fern is an Asplenium, but the specimen is insufficient for varietal identification.

GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 175, Victoria Street, S.W.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—*Secretary* Mr. A. E. Barron, The Royal Gardeners' Orphan Fund, Chiswick, W.

AN OLD SUBJECT,

BUT ever recurring. This is only natural when the subject matter appears on our tables at least three times a day, and four times if we belong to those folks who indulge in the luxury of "afternoon tea"—and who does not nowadays? Perhaps not every day, but certainly on those days when we welcome guests. The meal, pleasant and cheerful, is quite a modern institution, and, we were going to say, innovation, but we dare not go so far, as we fear the frowns of those daughters of "D., Deal," who may chance to read these dry, dull articles touching on the "Home Farm."

Well, you have all guessed what food or delicacy it is to which we refer. Food indeed, for butter is a form of fat which is most easily taken by women and children, and which is so necessary to their well-being. So much fat must be eaten every day if the balance of Nature is to obtain, and to many people the fat of beef, mutton, or bacon is most repulsive; therefore it is in milk, butter, or cream we must look for some good sound equivalent.

Milk as a rule is not taken in such great quantities that it can be relied upon to furnish all that is necessary. It contains ingredients of the greatest possible value, and we would advocate its larger use; but we would also add a word of caution—boil. We never (the wisest of us) can tell where may lurk the deadly microbe of consumption, but we have been assured by savants that the greatest danger arises from tainted milk. This danger is real, because it is most difficult to be absolutely sure of the healthy state of the cow from which it is drawn without a post-mortem—a difficult and inconvenient process which will not commend itself to many. Boiled milk and open windows, and we may hope to fight and worst the dread foe consumption.

But we are off the subject of fat, that pure, rich golden fat that trebles the value of the bread—that soaks lusciously in the browned toast, that lurks in the soft crumb of the muffin or teacake. To be perfect it should be free from taint or odour, should be so delicate in flavour as to be only suggestive of sources from which it sprang. But alas! can we say honestly this is the case with most of the butter exposed for sale, say in any market town in the United Kingdom? Sample it for yourself, and you will agree that most of it has a strong personality of its own, which in a few days develops into a distinct and not agreeable aroma.

There are of course many noble exceptions, and these not to be found entirely in cases where everything as regards the dairy is perfect. It is not the appliances any more than it is the pen that makes the poem. It is the moving spirit behind the appliances. We have seen the best of butter from dairies where the accommodation was limited in the extreme, and the dairymaid the busy head of a large family, and we have tasted butter from the dairies of great and noble that we could not quite class as anything but nasty. The country at large demands a regular supply of good butter of uniform quality—how is this to be obtained?

Not from the 1001 little dairies scattered over the length and breadth of the country do they turn out a uniform article either as

regards quality or colour. It is only by getting hold of the cream, or rather of the milk in the raw state, and treating it in factories or rather creameries that this desideratum is arrived at. In fact it might be classed as machine made butter; the milk is all mixed, the cream separated, and each pound and pat as like its brother as peas out of one pod.

Several questions suggest themselves to the thoughtful mind. The first is naturally the commercial one. Given the butter, what about the market? We answer with confidence, If Danish butter be so in demand, solely and wholly on account of its uniform character, why should not English-made butter meet the same demand? Mind, we must lay ourselves out to in the first place tempt our customers, and by fair charges and a good article insure their adherence. The public like straightforward dealing, and the public once caught must be kept.

Of course, there is the question of the necessary funds for establishing the creameries, but poor as Ireland is she has solved that riddle—co-operation does it. Lord Zetland, speaking the other day, thus touches on the subject. Previous to and in 1839 there was but one creamery in Ireland, with thirty members. In 1891 another was opened, and in 1898 there were no less than seventy-two co-operative working creameries, and fifty-one more in course of building. Of the number of members we can gain no exact report, but these figures speak for themselves; and these creameries exist in poor, down-trodden Ireland—Ireland which is said to be always a day behind the fair. Surely in rich, progressive England the thing might be worked. A Colonel Godson established one in the Ripon neighbourhood, which has been most successful, and two more have since been started quite near.

There has always been the question of the price to be paid for the farmer's milk, and the difficulty of transport from the farm to the creamery. Of course, if the concern were taken up by the farmers themselves, they being the chief shareholders, the difficulty of milk price would vanish into thin air; and we do not at all see why, if farmers can "run" seed-crushing and manure manufactories for the benefit of themselves, why they should fail to make a creamery go. As to the milk carriage, we should suppose the factory placed in a populous cow district, and could not some system of collection be worked? We fail to see why each individual farmer should cart his own few gallons when a general carrier might meet the wants of the case. This is only a crude suggestion, but one we think quite practicable.

There is another point to notice in connection with the price paid per gallon for milk. As milk varies so greatly, and the causes are difficult of control, should not the per-centage of butter fat form the basis of equitable payment? We think it would only be fair and reasonable.

Then, again, we suppose those dairies which supply the milk would come under notice of the sanitary inspector. He is a most necessary official; and might we suggest that a few "surprise" visits paid, say at morning milking time, might result in sundry divers reforms? We have heard of dirty milkers and dirtier surroundings; things are put into ship-shape by noon, and a casual visitor may never guess at half the abuses that exist.

WORK ON THE HOME FARM.

Mild and unnatural is the weather at the present time. Much as rain is wanted for the water supply, frost is absolutely essential if this year's Barley is to have a fair chance. We have been ploughing with a wet surface for want of something better to do, and without frost to make the land friable spring will find us with a poor seed bed.

A field of seeds is now being ploughed for Oats. The best use has been made of the old pasture for the sheep, and now we are turning down the sod 6 inches. This is deeper than we plough for Wheat; but on fairly dry soil we find that Oats do better on deepish ploughing, perhaps owing to the fact that they get a deeper root-hold and stand dry weather better.

The next work will be crossing fallows, and although it may seem rather early to begin we must take seasons as they come, and do the work

when it is ready and ignore the calendar. At any rate little mistake can be made, for should the hoped-for frost make its appearance the land will be laid more open to its influence, and should the weather keep open and dry the drag and harrow may soon be at work.

Wheat as a rule looks well, but some pieces are giving signs of grub by turning slightly yellow, and we find a patchy appearance of thinness; on walking over these patches we notice a hollowness, and the feet sink in at every other step. The chief remedy is rolling, and the rolling must be done as soon as possible. It is seldom possible to roll so early in the season, but if the roller be kept ready in the field, and horses are working at ploughing or other work over the fence, many opportunities may be found for rolling for part of a day, if not for the whole of it. We have often remarked to ourselves, when crossing Wheat in early February about eleven or twelve o'clock, "Dear me! why, we might have rolled to-day." The prompt use of the roller is a very important factor in the successful growth of Wheat on light land.

We are interested in the duel in a contemporary between two well-known authorities as to the value and capabilities of poor land. We agree with the ex-M.P. of long experience that there is land not worth cultivating, and we believe that the learned professor has yet to learn what poor land really is.

VINTON'S AGRICULTURAL ALMANAC, 1899.*

A CAPITAL sixpennyworth, worth the money for the sake of the portrait of that good old English gentleman, Lord Coventry, President of Royal Agricultural Society for this year. There is also a good likeness of Lord Londonderry, Chairman of Central Chamber of Agriculture. The two papers that strike us most are contributed by Sir W. Gilbey ("Table Poultry"), and one by Primrose Macconnell on "Feeding and Watering Cows;" but it is almost invidious to single out any special writer when all are so good. When the reader sees the names of such men as Prof. Wrightson, Mr. W. E. Bear, Mr. Soulby, Mr. T. Hill, Dr. Bowman, and others, he may be sure he will meet with subjects of great interest to him as a farmer, carefully treated and put in an interesting form.

OUR LETTER BOX.

Feeding Cows (Cowman).—For bran, substitute beanmeal; use Mangold now you are allowed to do so, but add a little Carrot if you can procure it. As hay forms a large portion of the food, see that the cows have plenty of chilled water, or at any rate the chance of it, four times a day. Do not turn the cows out.

REMARKS.

- 8th.—Fair day, with sun at times.
 9th.—Mild, sunny, and springlike.
 10th.—High wind and slight rain in small hours; a little sun between 8 and 11 A.M.; heavy showers with hail at 11, noon, and 10.30 P.M.; bright sun from 1.30 P.M. to sunset.
 11th.—Fine and generally sunny in morning, then overcast; slight rain at 0.55 P.M., and heavy rain from 3.45 to 4.15 P.M.
 12th.—Rainy early; dull and damp generally, but gleams of sun about 11 A.M.; heavy rain from 1.30 to 4 P.M.; clear night.
 13th.—Clear early, cloudy by 9 A.M.; incessant rain from 10.45 A.M. to 6 P.M., clear night.
 14th.—Fine and sunny all day; clear night.
 A very warm week for its date, no frost in the air, and much rain and wind.
 —G. J. SYMONS.

* 9, New Bridge Street, Ludgate Circus.

BARR'S SEED GUIDE FOR 1899 IS NOW READY,

And will be Forwarded Free on Application.

BARR'S SEED GUIDE contains a Select List of the best Vegetable Seeds and most beautiful Flower Seeds. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. SENT FREE ON APPLICATION.

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS contains a liberal assortment of the following useful vegetables: Beans (Broad and French Beans), Beet, Borecole, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrot, Cauliflower, Celery, Colewort, Corn Salad, Cucumber, Cress, Endive, Herbs, Leek, Lettuce, Melon, Mustard, Onions, Parsley, Parsnips, Peas, Radish, Salsify, Savoy Cabbage, Scorzouera, Spinach, Tomato, Turnip, and Vegetable Marrow.

Other Collections of Barr's Vegetable Seeds, 5/6, 7/6, 12/6, 42/-, 63/- and 105/-. These Collections sent carriage paid on receipt of remittance. Full particulars on application.

BARR'S CHOICE FLOWER SEEDS.—Our Catalogue contains a Select List of all the most beautiful Annuals and Perennials. Special Collections for all purposes, and many Sterling Novelties.

All Seeds sent Carriage Paid on receipt of remittance.

BARR & SONS,
12 & 13 King Street, Covent Garden, London
Nurseries: LONG DITTON, SURREY
(Surbiton Station, S.W. Railway).

ANT. ROOZEN & SON'S GUINEA COLLECTION OF VEGETABLE SEEDS

CONTAINS—

- | | |
|---|---------------------------|
| 16 Pints Peas (including A1, Marrowfat, and Late Queen) | 2 Pkts. Endive |
| 6 Pints Broad Beans | 1 " Gourds |
| 2 Pints Dwarf French Beans | 1 " Kohl Rabi |
| 1 Pint Scarlet Runner | 2 " Leek |
| 1 Packet Asparagus | 3 " Cabbage Lettuce |
| 2 Pkts. Beet | 2 " Cos Lettuce |
| 2 " Borecole | 2 " Melon |
| 3 " Broccoli | 6 ozs. Mustard |
| 2 " Brussels Sprouts | 4 " Onion |
| 3 " Cabbage | 2 Pkts. Parsley |
| 1 " Capsicum | 2 ozs. Parsnip |
| 4 ozs. Carrot | 4 " Radish |
| 2 Pkts. Cauliflower | 1 Packet Salsify |
| 2 " Celery | 2 Pkts. Savoy Cabbage |
| 1 " Couve Tronchuda | 2 " Scorzouera |
| 4 ozs. Cress | 6 ozs. Spinach |
| 3 Pkts. Cucumber | 6 Pkts. Herbs |
| 2 " Egg Plant | 2 " Tomato |
| | 4 ozs. Turnip |
| | 1 Packet Vegetable Marrow |

For other Collections from 10/- to 100/- see our Seed List
Orders for VEGETABLE SEEDS of 20/- and upwards sent Carriage Paid.

Orders for FLOWER SEEDS of 3/- and upwards free by Post.

LIST will be sent post free on application to their Offices at OVERVEEN, nr. HAARLEM, HOLLAND, or to their General Agents,

Messrs. MERTENS & CO.,
3, CROSS LANE, LONDON, E.C.

No. 970.—VOL. XXXVIII., THIRD SERIES.

NOVELTIES RAISED AT WINDSOR AND OSBORNE.

It is Messrs. CARTERS' privilege to offer the following new and choice productions to the notice of gardeners and private cultivators.

BRITISH QUEEN MELON.

Raised and named by Mr. OWEN THOMAS, Supt. of the Royal Gardens, Windsor. Awarded the First-Class Certificate R.H.S. Pronounced by the Committee to be not only the very best white-flesh melon ever submitted, but the richest flavoured of any colour. Awarded the Gold Medal of the Royal Caledonian Society in association with other fruit exhibited by H.M. The Queen.

In sealed packets, price 2/6 and 3/6 each, post free.

ROYAL OSBORNE CUCUMBER.

A valuable cross between the Rochford and an improved type of Telegraph, raised and named by Mr. GEORGE NOBBS, Head Gardener to H.M. the Queen at Osborne. In our opinion it is one of the best all the year round varieties introduced in recent years.

In sealed packets, price 2/6 & 3/6 each, post free.

ILLUSTRATED CATALOGUES, POST FREE.

WE HOLD THE ENTIRE STOCK OF SEEDS
OF THESE TWO NOVELTIES.

CARTERS,

The Queen's Seedsmen.

Only Address—

237, 238 & 97, HIGH HOLBORN, LONDON.

The 32nd Edition is Now Ready.

200 PAGES. 150 ILLUSTRATIONS.

PRICE SIXPENCE, POST FREE.

(By Parcel Post—it is so large).

EVERY AMATEUR SHOULD POSSESS A COPY.

AN ABRIDGED EDITION OF OUR CATALOGUE CAN BE HAD FREE ON APPLICATION.

CHRYSANTHEMUMS.

Our Stock is perfectly clean. We never had Rust or Disease in our Collection. Cuttings from 1/10 per dozen.

SWEET PEAS.

All Standard Named varieties are offered per 1/2-oz. Packet. From 3d. per Packet.

SEED POTATOES.

These are quoted in small lots, and Carriage Free to destination.

DOBBIE & Co.,
SEED GROWERS AND FLORISTS TO THE QUEEN,
ROTHESAY.

Journal of Horticulture.

THURSDAY, JANUARY 26, 1899.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

LIFE AND FOOD.

THE use of the terms Life and Food, when applied to plants, implies the fact that vegetation not only lives, but requires food for its sustenance. The life and appetite of a plant are simpler, but not less peculiar, than those of an animal. The microscope and chemical analyses unfold to a certain extent cell formation and development in the character of the substances employed in building up plant structures, the form of mechanism adopted in the first stages of growth, and most of the chemical changes and transformations which occur in subsequent development.

The vital force of the plant controls and guides its activities so as to make them effectual. By this vital force, and through the medium of active microscopic cells, all the changes that occur in building up plant structures and products take place. Some plants among the lower orders of the vegetable kingdom are so simple in structure that their whole organism consists only of a single cell. All plants belonging to the higher orders consist chiefly of globular or angular cells, and all growing parts of a plant, without exception, are aggregations of minute living cells.

Upon closer observation we find that the plants of a single cell consist simply of a cell wall, which is lined with a smooth homogeneous mass, called protoplasm, and is filled with fluid. This simple cell, thus constituted, has been termed the "workshop" in which the processes of growth and development are carried on; and during the seasons of growth it is the scene of intense activity. Simple and insignificant in size and structure, this tiny one-cell plant is the miniature of the massive tree or shrub that overshadows it. The larger plant is only an aggregation of cells piled on cells, each one of which carries on the same kind of work that is performed by its tiny prototype.

Cell structure and development, thus briefly described, is found to be very much the same in all plants, provided the cells are young and belong to the growing parts. Plant cells show no apertures under the microscope, and yet they are readily permeable to liquids.

No. 2626.—VOL. C.—OLD SERIES.

In examining the structural parts of plants, such as have ceased to grow, as in the full-sized leaf, the perfectly formed wood, we find that the cells do not correspond to the description just given. In the external form, thickness and appearance of the cell wall, and especially in the character of the contents, there is infinite variety. But this difference is simply the result of changes in the original cells during the processes of growth and maturity.

Thus, many of the lower orders of plants are constituted entirely of cells, but in higher orders, as in flowering plants, these simple cells are developed into cellular tissue, wood tissue, and vascular tissue. The plant, then, when fixed in the earth, consists of the root, stem, and leaf, all of which are developed by the proliferation or generation of cells from the parent cell or cells in the germ vesicle cells of the seed.

We have now to consider the nature of the food used by the plant cell. This food consists of the elements of the atmosphere, and of the mineral or inorganic substances of the earth. Wonderful and mysterious, indeed, is the power of the plant cells; under the influence of the sun's rays to separate from atmospheric air the compound known as carbonic acid gas, and to disintegrate and to appropriate to its use the elements contained in the hardest rocks.

While we know the elements essential to plants as food, and the forms of combination of the elements best adapted to the growth of plants, we are almost entirely ignorant of the methods by which they acquire their food, and build up such tissues as cellulose, starch, albumen, oil, fat, resin, and other matter which constitute their structure and products. This power of appropriating and assimilating elements must be largely referred to the vital chemistry of the plant.

It was thought at one time that plants lived on humus or vegetable mould, and that the mineral substances found in their ashes were accidental or extraneous; but we now know from actual research that mineral substances enter into the vegetable structure in solution as food, and that plants cannot exist without them. Yet it is true that they are required in very minute proportions in comparison with the carbonaceous and nitrogenous food of the plant.

In reality by far the largest portion of the bulk of plants is made up of a combination of organic substances; about 95 per cent. of so-called atmospheric food, such as carbon, hydrogen, oxygen, and nitrogen; the remaining 5 per cent. is obtained from the soil, and is called mineral food, consisting of potash, soda, magnesia, lime, phosphoric acid, sulphuric acid, and iron. These are the elements considered to be the most essential as plant food. It is, however, only nitrogen, potash, and phosphoric acid, which have aptly been called the golden tripod of plant life, that the gardener need, as a rule, trouble himself about, except in certain cases, when the element lime becomes absolutely necessary. These are the substances that should rule the selection and purchase of artificial manures.—J. J. WILLIS, *Harpenden*.

BARK PRUNING AND LIFTING OLD PEAR TREES.

BARK pruning, or the ringing of fruit trees with a view to bringing them into early bearing, is a method by which temporary returns may be obtained, but the practice has not, I think, much to recommend it in a general sense. Trees prone to extreme vigour produce roots few in number and of a size proportionate to that of the branches, and vigorous growth often indicates deep root burrowing in the subsoil.

So long as this thong-like root growth is allowed to go unchecked, there is not the remotest chance of getting those of a fibrous nature in quantity, or near the surface, and I cannot see what beneficial influence can be brought to bear on the production of root fibres by ringing of the main stem or branches. It is easy to understand that in a young vigorous tree ringing of the bark would so check the flow of sap and the excessive growth as to promote that of a more fruit-bearing character for a time. Except in such cases where access to the roots is rendered impossible from local circumstances, I should not consider it advisable to adopt ringing as a substitute for root-pruning, and I think it will be found that the course taken by Mr. Picker (page 49) in dealing with his old deep-rooted trees is the better one.

By severing tap roots of large size a great check is given the tree, and by enriching the surrounding soil, mulching and watering in dry weather, roots of a fruit-producing character are sure to follow in due course. A stone slab of 18 inches square could not serve any useful purpose, and would prove a hindrance rather than otherwise in root-

pruning even a much younger tree. A layer of dry lime rubble 9 inches thick at a suitable depth has been found a good provision against deep root burrowing in Pear trees. The course advised by the Editor of reducing the branches and laterals would much assist the trees after the severe operation to which they have been subjected.—W. S.

ASPARAGUS.

It is difficult to write anything new in respect of the culture of this vegetable, but considering the high estimation in which it is held both in large and small establishments, no apology should be necessary for a few remarks on a well-worn subject. Except on very strong land Asparagus is not difficult to grow. In light sandy soils, given generous treatment, it will thrive like a weed, reproducing itself in all sorts of odd corners, and with such ground expensive methods of preparation are not needful; in fact, simple practice leads to profitable results. With clay the case is totally different, special beds must be formed. The winter is the best time to commence this operation. If the soil is very strong it may be found advisable to remove some of the original, refilling with old refuse from the potting sheds, road scrapings, leaf soil if procurable, ashes from rubbish fires—anything, in fact, having an opening tendency. If the land is not well drained, this must be provided by some means if good crops are to result.

There is still to my mind no better method of arranging Asparagus beds than the old one of having three rows of plants in a bed 5 feet across, one row through the centre and the others 18 inches from it on each side, and having alleys between about 15 inches wide. The materials I have mentioned above should be trenched into the soil, and as far as possible be dug over two or three times during the winter, to thoroughly mix the whole. I am aware that some very good gardeners grow their Asparagus on a different system—viz., in rows from 6 to 8 feet apart, with other crops between. This is, I think, more suitable for large places; in a small garden the old-fashioned beds count very much for tidiness, and are preferable.

On light, well-manured land seeds of Asparagus may be sown in April, in drills 3 or 4 inches in depth and 18 inches apart. If this is done, every fourth row may be taken up at the end of a year, and the spaces thus formed will constitute the paths. The young plants will eventually require thinning to about 15 inches asunder in the rows. If the seeds were sown thinly in the first instance, they may all grow together the first year, but if at all crowded they should be thinned when 2 or 3 inches in height. As is generally recognised now, planting is best done in spring, when the crowns are beginning to move. Open sufficient ground to allow the roots to be spread out fully and evenly, and, when finished, the crowns may be about 3 inches below the surface.

On more than one occasion I have been asked when to cut down Asparagus, almost as if there were some mystery about this process. The old growths, as a rule, may be cut the first or second week in November, but except on the score of neatness (of course that is important) there is no need for extreme haste. It must be remembered the sooner the ground is cleared so much the earlier may a good mulching of manure be applied if thought necessary. Is it, however, really essential that Asparagus should have as much manure as it often gets? True, it is a gross feeder, still there is usually the salt in spring as well as the autumn dressing. A friend of mine having read in the *Journal* of a gardener who was in the habit of using the ashes from the refuse fires was led to try these each alternate year with most excellent results.

Scarcely enough importance is, I think, attached to watering in dry seasons. I took charge of some twenty year-old beds in the cutting season, and there seemed to be the greatest difficulty in maintaining a supply for the house. We gave a light dressing of nitrate of soda, and a thorough watering, repeating the latter as needed. In a fortnight there was ample produce, while in three weeks Asparagus was being given away. The nitrate was repeated once or twice afterwards, and a good supply was easily maintained.

Forcing Asparagus is not a hard matter if proper convenience is at hand for heating. I have seen blanched stems cut from a Mushroom house which were much appreciated, but as a rule it is best grown in a frame, so that the light may have the necessary effect, and good green heads be produced. However showy the great white bundles of French produce one sees in shop windows may be, I should certainly prefer good green tops cut just below the surface of the soil, about 6 or 7 inches in length, with enough white left on to serve as a "handle."

In my opinion salt is sometimes given too freely to Asparagus. A light dressing is better than a very heavy one so long as enough is applied to kill weeds. The tendency of salt is to lower the temperature of the soil, and this is not desirable. To sum up, Asparagus should have the best of culture, be kept clear of weeds, and then the grower will be justified in expecting good succulent heads; whether his object is the market or an employer's table.—J. SHALFORD.

CYPRIPEDIUM WOTTONI.

THE collection of Orchids so excellently tended by Mr. H. J. Chapman at Cambridge Lodge, Camberwell, for R. I. Measures, Esq., is peculiarly rich in *Cypripediums*, many of which are hybrids that have been raised there. Naturally the older species and varieties are splendidly represented, and we have on more than one occasion had the pleasure of examining the plants, and reproducing some of the choicest of the flowers. It must not be thought that *Cypripediums* are the only Orchids grown, for such is by no means the case, as *Masdevallias* are superb, while *Cattleyas*, *Laelias*, *Odontoglossums*, *Dendrobiums*, and others are little if any inferior. At the present moment, however, we would place before our readers a representation of *Cypripedium Wottoni* (fig. 12), to which the Orchid Committee of the Royal Horticultural Society recommended an award of merit on November 8th last. As a glance at the woodcut will suffice to prove, the flower is singularly massive. It resulted from a cross between *C. bellatulum* and *C. callosum*. The dorsal sepal is very broad and substantial, the colour being pale claret with darker veins, paling gradually towards the white margin. The fine pouch is deep claret, while the petals are a lighter shade of this colour, with darker suffusions and heavy spots extending from the base to the centre.

A FLORIFEROUS CYPRIPEDIUM.

There is at the present time in one of the Orchid houses at Rangemore a *Cypripedium* (named provisionally *Venubel*) bearing six flowers on one spike, five fully open and one developing. Can any of your readers tell me if such an event has occurred before to their knowledge? I know it is nothing unusual for a plant to have many flowers develop one at a time, such as on *C. Sedeni*, but I think this one having five flowers open simultaneously must be something unusual.—J. DAWSON.

SACCOLABIUM GIGANTEUM.

This pretty and interesting plant has again flowered well this season, and the dense racemes of small blooms have a bright appearance and scent the house wherein they are grown. *S. giganteum* thrives best in a high temperature, and owing to the large size of the roots, fairly roomy pots or baskets should be allowed, these being suspended as near as possible to the roof. Nothing but sphagnum and charcoal need be used as compost, and the plants must be kept in a medium state as to moisture while the flowers are open. When these are past and the plants have taken a slight rest they commence to grow, and increased heat and moisture are required.—H. R. R.

DESSERT APPLES.

I HARDLY think Mr. Pieker is as fortunate in his selection (on page 4, January 5th) of varieties for dessert as in the kitchen section. He rightly places Cox's Orange Pippin at the head of the list. No Apple equals it for flavour; in my opinion it is much superior to Ribston Pippin, which is in many instances decidedly dry. Cox's is, as a rule, a constant bearer, except perhaps when an exceptionally heavy crop is borne on the trees one year, it is much lighter the next. Where the trees are large it is not always possible to thin the fruit, hence some weakening must take place, especially if stimulative food is not freely supplied. In no form does this Apple succeed better than as a half-standard. In this form a handsome tree is made; the long flowing branches sweep the ground and give an extremely wide area of fruit-bearing parts, much more so than can any bush-grown tree. Where space is available plant half-standards and allow the trees to develop freely without much shortening of their branches after the foundation is laid.

Every word of what Mr. Picker says of Worcester Pearmain is correct in my ear also. The quality is quite third-rate, but people will have it on account of its colour. If I were compelled to grow one dessert Apple only for sale I should select this, treat it freely, and expect satisfactory results.

Kerry Pippin is much too small in my opinion for either home use or market; certainly I should replace this with Benoni, which is not

nearly enough known as its merits deserve. The fruit much resembles King of Pippins in shape, but is perhaps brighter in colour, while the flavour is superior, and, what is more important than all, it comes in at a time when dessert Apples are scarce—just before King of Pippins is ready and after Worcester Pearmain is finished. The tree is an upright grower, a point in its favour for market work, as it can be planted closer together than many sorts.

Irish Peach I do not think is worthy of its place in Mr. Picker's list; certainly for market I have found it quite useless, its dull appearance and soft flesh entirely putting it out of the question. I should replace this with Devonshire Quarrenden, which always finds a ready sale and quick consumption at the home table.

King of Tompkins' County growing in the open has not been a success with me, as it repeatedly fails to give anything like a reasonable return. I hardly think Dutch Mignonne is good enough in quality as a dessert Apple. I should replace these two with Lady Henniker and Claygate Pearmain, both for home use. Allington Pippin, Gravenstein, and Trumpington I do not know enough of to express an opinion.

FIG. 12.—CYPRIPEDIUM WOTTONI.

Blenheim Pippin I consider one of the best Apples in cultivation. When established as a standard it produces a crop more certainly perhaps than any other variety grown. I used not to recommend it on account of its slow growth and similar fruit-producing quality, but having had twenty years' experience with trees I have altered my opinion, and now recommend it always. Deep planting in strong soil is certain to result in failure, as the branches become affected with canker. Plant on the surface and mound around it, treat liberally at the roots, allow the growth to extend freely, but thinly, and success with this Apple is certain to follow.—E. MOLYNEUX.

MR. PICKER certainly distinguishes between Apples for home use and for market, otherwise some varieties which he mentions on page 4 would scarcely have found a place in his selection. But apart from those included, why is one of the best market Apples for eating uncooked omitted? In a strong tenacious loan in which Cox's Orange Pippin is not happy, the crimson-cheeked Quarrenden grows and bears as well as Worcester Pearmain, and the fruits find acceptance with general consumers.

Baumann's Winter Reinette is approved for market, no doubt because of its colour and easy growth, but denounced for home use

because of its inferior quality. It is in my experience the most disappointing Apple of modern times for eating in either a cooked or uncooked state. It is as judged for quality absolutely bad—nasty; and yet the Royal Horticultural Society place it in their list of dessert Apples in their "Rules for Judging." It is unworthy of its position there, and ought to be expunged.

Mr. Picker describes Dutch Mignonne as "an excellent Apple for private use." I have grown it for years, but have never found it to find favour at the dessert table. The tree bears abundantly, and is handy for affording a basketful of fruit now and then for the servants' hall, or it would have been cut down and grafted long ago.

Gravenstein is an ideal Apple for persons with bad teeth, as the flesh is so tender and melting, also pleasantly flavoured. Mr. Picker correctly describes the true Gravenstein. I have seen trees and fruit under this name which are not true, and the genuine variety does not seem to be grown in many gardens.

Margil Mr. Picker correctly describes as a first-class dessert Apple, and such it undoubtedly is. It requires free generous soil and a sheltered position. In appearance it suggests a combination of American Mother and Ribston Pippin. In quality it is as good as either, but differs somewhat from both. It is not a market Apple, but a choice dessert fruit.—A LINCOLNSHIRE GROWER.

TOMATO CULTURE.

(Continued from page 44.)

In the nursery catalogue of Messrs. Thomas and James Backhouse, York, 1827, Tomato is not mentioned, but is referred to as a "culinary" under the name of Love Apple, *Solanum Lycopersicum*. Mr. W. Masters, in "Hortus Duroverni," a catalogue of plants and seeds, 1831, includes it among "flower seeds" under the specific name of *Lycopersicum esculentum*, Red Love Apple, and enumerates a variety, *L. c. chrysocarpum*, yellow-fruited, both tender annuals, growing 3 feet in height, flowering or fruiting from July to September, and natives of South America. Loudon's "Encyclopædia of Plants," new edition, edited by George Don, F.L.S., 1858, still has *Solanum Lycopersicum*, Love Apple, and in the footnote gives the name in French—viz., Tomato, which accounts for the name Tomato, and the market growers "Toms." Loudon says:—"Its use for sauce in this country is greatly on the increase, and it is cultivated to a considerable extent near London, against walls and artificial banks, being raised on a hotbed and transplanted like other tender annuals." This, as the editors and revisers were only responsible for the supplements of the Encyclopædia, would be written by Loudon in 1829. Then, according to MacIntosh's "Practical Gardener," Love Apples were as well grown outdoors, if not better than now, especially near London, to which the culture appears to have been for a considerable time mainly centred. Thompson's "Gardener's Assistant," 1859, supersedes Love Apple by Tomato, and says a wall with a south aspect "is indispensable in cold localities, both in England and Scotland" for it outdoors. In the same excellent work the author says, "The Tomato is very rarely forced in this country. Fruit may, however, be produced as early as April or May by sowing in October in pots of light rich soil placed in a Pine stove." The first separate work on "The Tomato, with Cultural Directions for Maintaining a Continuous Supply of Fruit," was published at the *Journal of Horticulture* office in 1881, the author being Mr. W. Iggulden.

Tomatoes can be easily grown, either indoors or outdoors. It is no use making excuses about means, for as the author of "The Tomato" observes, "Those who expect to have everything 'cut and dried' for them, or, in other words, expect facilities of the best description for every undertaking, are very liable to be out-distanced in the 'long-run' by those of a more inventive and persevering turn of mind."

The culture of the Tomato may be divided into indoor and outdoor, and these again be subdivided into several sections, which will be best referred to in successional order of crop production.

INDOOR CULTURE.

The Tomato requires a light, airy, well heated structure, and so placed as to receive all the sun possible from its rising to setting at all times of the year. A lean-to, or, better, a three-quarters span-roof small house or pit facing due south, answers for early crops. Span-roofed houses, however, are most in vogue, their low sides, whether of masonry or wood, being a consideration, while they expose a large surface of glass to the light. They range in width from about 10 feet to 30 feet, and in length from 20 feet to 100, or even 300 feet respectively. The small houses are usually found in private establishments, a house 10 feet wide and 20 feet long affording a supply of Tomatoes equal to the requirements of a fair-sized family for two or three months. Such houses or pits are of the ordinary type used for growing Cucumbers, Melons, forcing Strawberries, French Beans, or growing small plants for decorative purposes, and the most useful a gardener can command apart from the Peach houses and vineries. They are

sometimes placed with the ends east and west, when the southern side of the roof proves much the best for early Tomatoes. In other cases the houses have the ends north and south, when there is not much to choose between the east or west side of the roof; but I think the east has the advantage if anything in earliness.

Large structures have considerable advantages over small houses. 1, They cost less relatively to construct, there being a much smaller extent of sides and ends. 2, They entail less expense in heating appliances, narrow houses requiring more piping than wide ones. 3, Enclosing a larger body of air they are less affected by climatic vicissitudes, neither heating so quickly by the sun, nor losing heat so rapidly when it is obscured. 4, The temperature is more evenly and economically maintained under any and all circumstances, so that the market grower, with his acres of large Tomato houses, has an immense advantage over the private grower with his small houses. For this reason, and often no other, Tomatoes can be more cheaply bought than grown in the heyday of the Tomato season; but where there are a number of houses, plant and fruit, the heating of a small house makes little difference, and the fruit comes in so much earlier when given the best advantage of aspect that the big house is easily superseded.

Besides, the large growers—that is, the most "cute" of them—have small houses, extra well heated, as well as monster structures, that may well be called "fields" in comparison with the "gardens" of the small growers, and they utilise these pits or small houses for raising the plants. The market grower has still the further advantage of drafting his plants as they grow into the all-light structures, where they cannot do anything but grow into sturdy, short-jointed, early fruit-showing specimens, whereas the private grower has to make shift with any positions that are vacant, and as near suitable as circumstances permit. Still difficulties only exist to be surmounted, and by hook or crook the patient plodder overcomes disadvantages by considerable scheming, of which the large grower has not the least inkling, and after all secures a good result with mostly far less trouble from diseases. I think it desirable to make these distinctions between the market grower and the private gardener, in order to prevent confusion, and place both on an equal footing as to expectations and results from commanded means.

Early Crops.—The fruit is most valued during the winter and early in spring, but it, like winter Cucumbers, is far easier to write about than to secure. To try, cuttings rooted in August in small single pots should be grown in the full light and repotted as necessary until a 10 or 12-inch size is reached, which will be sufficiently large for fruiting them in. If it is intended to plant in narrow borders or boxes the plants should first be grown in pots, and not be transferred to the final quarters until some of the earliest fruits are set, then there is a chance of some winter fruit, not otherwise, for the plants are so liable to grow to leaves and cease to set and swell fruit in November and December and January.

Those who have such plants, often healthy enough, may, if in pots and tall, root the promising shoots in gentle heat and grow them, or if the stock is planted out and the growths trained not far from the glass, the leaders may be allowed to extend where there is room. When strong bunches of well formed flowers open on these particular care must be taken in fertilising them, transferring the pollen from the stamens to the stigmas about midday. A few side shoots being also laid in, these commence flowering in due course, and give a succession of fruit. A dry atmosphere is important, the temperature not falling below 55° at night unless very cold, and keeping 60° to 65° by day in dull weather, and 70° to 75° with gleams of sun. Give a little air during mild days, and do not pinch the plants for fresh air when the sun admits of free but judicious ventilation, and water very sparingly.—G. ABBEY.

(To be continued.)

EARLY PEAS.

THE extremely heavy rainfall of the present month will retard the usual early sowing of outdoor Peas. The spring prospects, too, of other vegetables are not of an assuring character in point of variety or quantity, and there will be need for prompt action in preparing for a crop at the earliest date.

Various means are adopted in forwarding Peas under glass for outdoor planting, some being very careful that none, or but the slightest disturbance of the roots happens. It is surprising how quickly Peas resume active growth when planted out of shallow boxes during genial weather in spring, and a slight check thus brought about is soon overtaken.

It is a mistake to hurry the growth of Peas in forcing houses; time is gained by placing them in cold pits or cool houses, where their advancement is more natural. Grown under these conditions there is little trouble in the final planting, because the course of hardening is so simple, and between now and the middle of March there is ample time to get a sufficiency of top growth, while the roots will not be so closely matted as to render planting difficult. The early and hardy Marrow varieties are best for this sowing.—W. S.

DEATH OF MR. JOHN LEE.

At last, after an unusually long and, in the fullest sense of the term, honourable career, one of the most respected and trusted of horticulturists of the century has passed away. "John Lee, of Hammersmith," as he was familiarly called by his many friends, over at least two generations, during which he was a leading personality in the nursery trade, died at the residence of his son, Warwick Gardens, Kensington, on Friday, the 20th inst., in the ninety-fourth year of his age.

The deceased gentleman retired from active business in 1877 after fifty-four years of uninterrupted work, and several of our readers will remember the complimentary dinner given to Mr. Lee at the Horticultural Club on February 15th of that year, though some of them, alas! predeceased the then guest of the evening. Among these may be mentioned the names of the Chairman and Vice-Chairman, Dr. Hogg and the Hon. and Rev. J. T. Boscawen, also Mr. John Wills, who decorated the tables so superbly, Mr. B. S. Williams, Mr. G. Deal, and Mr. Charles Lee. The survivors will remember the feeling and appropriate terms in which the Chairman spoke of his long friendship with Mr. Lee, and wished him on the part of himself and those assembled long life and happiness to enjoy his well earned rest; nor will they forget the extraordinary ovation which Mr. Lee received when he rose to return thanks for the compliment paid him by his friends.

It is not too much to say that the quiet, unobtrusive manner of Mr. John Lee, his innate gentleness of demeanour, and his uprightness of character, placed him on the highest pedestal of popularity in assemblages of horticulturists. Though never effusive, those friends who had long enjoyed the pleasure of his society knew full well that he possessed a warm and honest heart. In discussions, of which prominent men are often the victims, never a word was heard about John Lee that would not have been said in his hearing; and, correlatively, never was heard from his lips a sentence which could be construed as in the least degree a reflection on any of his contemporaries.

The esteem in which he was held was never more strikingly manifested than on the occasions of the anniversary dinners of the Gardeners' Royal Benevolent Institution. His connection with this important Charity dated from its establishment in 1838, and for years, and until far advanced in the "eighties," there was no happier man at the festive board than he. When the "father" was called up a momentary stillness occurred which seemed to make the tremendous reception accorded him the more crushing. As the tall spare form appeared all eyes were turned towards him, and ears were intent to catch every word that fell from his lips. Not that he was eloquent, but because it was felt he was better than that—sincere. He was one of those men who could say a good deal in few words, and these carried with them the conviction that the Institution had no firmer, truer friend on its roll than the "father—John Lee;" and, as recorded on page 64, he has left the splendid charity £100 free of legacy duty.

Though, as stated, the deceased gentleman retired from active business in 1877, when the firm was, and is, known as Charles Lee & Son, we believe he, on the death of his junior brother Charles in September, 1881, took for a time a share in the management, to lessen the strain suddenly thrown on his nephew and present head of the business, Mr. William Lee. Long after that Mr. John Lee attended the meetings of the Fruit Committee at the Drill Hall, as well as at Chiswick, when his ripe experience was of great value in estimating the merits of the products inspected, and his observations, as they were entitled, always carried weight with his colleagues.

The firm of which the subject of these notes was for a great length of time the head, is of historic character, and has been identified for something like a century and a half with the progress of horticulture in this country. James Lee, a native of Scotland, was one of its founders about 1750. He was for some time with Phillip Miller at the Chelsea Botanic Garden, and afterwards gardener to the Duke of Argyll at Whitton, Middlesex. In conjunction with Kennedy, then gardener to Lord Bolton at Chiswick, he commenced business at The Vineyard, Hammersmith, and which ultimately became one of the largest in the kingdom. James Lee was also a botanist and author, and died in 1797. He is credited with the distribution of the *Fuchsia* in England. This is the story as we find it recorded:—

"The *Fuchsia* was introduced by the casual observation that a strange flower had been seen at Wapping. Mr. Lee, nurseryman, Hammersmith, was told of a flower coloured crimson with a fold like purple

FIG. 13.—MR. JOHN LEE.

ribbon in its centre. He hastened to Wapping, found the plant, and, for 8 guineas, induced the owner to sell it, though she wished to keep it because "brought from the West Indies" by her husband. Mr. Lee propagated it rapidly from cuttings, and in the following year sold 300 plants for as many guineas."

This was long known as *Fuchsia coccinea*, but is said by the Kew authorities to be *F. magellanica*, introduced in 1789, while the true *coccinea* is a modern introduction—1878. James Lee is portrayed with a spray in his hand, the flowers of which he is examining, botanist-like, with a lens for noting the essential characters. It is not a *Fuchsia*, but appears to be an *Oenothera*. He is thus on the track in classifying his then new plant, for both belong to the same natural order—*Onagraceæ*.

The Vineyard Nursery, where the foundations of the firm were laid, has, like many other old metropolitan nurseries, fallen a prey to the builders and is eaten up. The present nurseries are at Isleworth, Feltham, and Ealing, and, as imposing exhibits have shown, are rich in ornamental trees and shrubs. But the building invasion is moving on, and will conquer in time as sure as death has conquered the graud old man whose remains were interred in the Brompton Cemetery on Tuesday last in the presence of sorrowing friends. Besides the members of the family we noticed among those who paid a last mark of respect to the deceased gentleman, Mr. Harry J. Veitch, Dr. Maxwell T. Masters, Mr. R. A. Mulligan Hogg, Mr. N. N. Sherwood, Mr. G. J. Ingram, Mr. G. Monro, and Mr. A. Dawkins.

WINTER IN THE SAHARA.

A CONTRAST indeed to the vagaries of our island home. Though even in this arid and eternally scorching clime, where in most parts rain is an unknown quantity, the nights can be tolerably cold, certainly extremely so if reckoned in contrast to the terrific heat on the daytime. As regards the flora of the Sahara proper, with such an indispensable as above mentioned wanting, it must of necessity be but sparse, and for the most part conspicuous only by its absence; but there are delightful exceptions.

In and around the oases there is variety in abundance, and much that affects readers of "our Journal," if only as regards their appetites. In these beautiful spots, surrounded as they are on all sides by the pitiless desert, Nature seems to endeavour to make amends for the destitution around, and even outdo herself in extravagant vegetation. Carefully irrigated and cultivated to the highest degree, they are interesting to the traveller and student of Nature to no ordinary extent. For my part, during a sojourn at Biskra a few years ago, in the winter, I was enabled to study the products and trade of the oasis, and many features of desert life. At El Kantara, another oasis and gorge of surpassing loveliness, and of romantic surroundings, some 100,000 Date Palms (there are over double this number at Biskra) are grown. Besides rice, millet, and many other grains, numbers of fruit, flowers, and Ferns, some cultivated, some wild, feast the eye in their bountiful profusion. Let it not be supposed, moreover, in such an out of the way place that there are no ulterior attractions.

In addition to the climate, which probably is unrivalled for those inclined to consumption and asthma, Biskra is unusually favoured in having a range of mountains (the Aure's), where the gazelle and other game can be pursued, and from the summit of which a wonderful panorama of the Saharan desert may be viewed. Then there are several other oases within easy reach by camel or on foot in the immediate vicinity. In a narrow lane of one of these the writer was making a lunch of Dates as he walked along (it is astonishing how sustaining they are when on the tramp), when an attractive little Arab boy joined company and carried on a kind of conversation with the aid of the scant smattering of Arabic the writer possessed. On parting a few Dates were offered this scion of the desert, and though looked at with evident desire, were yet firmly refused, owing to its being the Fast of Ramadan, when from sunrise to sunset nothing must be consumed. This is a matter they are extremely strict about.

In one direction, within, I think, a day or so from Biskra, the mirage is accommodately *en evidence*, and a short half day's trudge across the sand brings one to the very celebrated hot sulphur springs of Hammam Salatin. Then there is always the chance of coming across a caravan. The camel was an endless object of mystery to me. It apparently lived on nothing, and as if making belief to execute a good square meal on tiny coarse tufts of Rush struggling among the stones and sand.

I must, in closing, make mention (though not in the Sahara) of the beautiful Maidenhair Fern of enormous size I found in the most prodigal quantities deep down the wild gorge above Blida, a most interesting place in a spur of the Atlas Mountains. Here, too, numbers of monkeys abound. A sight more appealing to an Englishman in this same place is the fine stud of some five hundred Arab, Syrian, and Saharan thoroughbred stallions; while, to the lover of fruit culture, the extensive Orange groves of every known shape, size and flavour are an attractive study.—T. A. CARNEGIE CHEALES.

WEATHER IN LONDON.—Sunshine, rain, and wind have held sway during the past week in the metropolis. On Thursday last some rain fell, as did it heavily on Friday and Saturday. Sunday was very bright and pleasant, and Monday turned colder with a slight night frost. Tuesday was dull, followed by a sharp white frost, while Wednesday opened bright and bracing.

— ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, January 31st, in the Drill Hall, James Street, Westminster, 1 to 4 P.M. This will be the last meeting of the 1898-99 Committee, the new ones coming into office on February 14th. A lecture on "Twelve Months Among the Orchards of Nova Scotia" will be given by Mr. Cecil H. Hooper, F.R.H.S., at three o'clock.

— DWARFISM IN PINES.—A curious instance of dwarfism in Pines is recorded by Mr. C. E. Bessey of the University of Nebraska. On Green Mountain, near Boulder, Col., he found in a crevice of the rock at the summit a Pine tree (*Pinus albicaulis*, Engelm) only 13 centimeters (under 3 inches) high, and 5 millimeters (one-fifth inch) in diameter. It had no branches, and bore a single tuft of needles at the top. Nevertheless, says the "American Cultivator," it showed twenty-five distinct annual rings, and was therefore twenty-five years of age.

— BOURNEMOUTH AND DISTRICT GARDENERS' ASSOCIATION.—At the meeting of the above Society held on Tuesday, January 17th, and presided over by Mr. G. Omer Cooper of Reading and Boscombe, Mr. H. J. Jones of Lewisham gave a "Chat on the Chrysanthemum." This proved most excellent and up to date, and dealt with their culture from the cutting to the exhibition table, and occupied upwards of ninety minutes in delivery. Mr. Jones received a most cordial welcome on his first visit to Bournemouth. After a short discussion he was accorded a hearty vote of thanks. The lecture was repeated before the members of the Parkstone Society on the following evening.

— LIVERPOOL HORTICULTURAL ASSOCIATION.—On Saturday evening the twelfth annual dinner and social evening was held, when some 110 members and friends sat down to an excellent repast. After dinner the chair was occupied by W. Fletcher Rogers, Esq., the esteemed Hon. Treasurer, the following firms being worthily represented and adding much to the enjoyment of all present—viz., Messrs. R. P. Ker and Sons, Aigburth; Messrs. T. Davies & Co., Wavertree; Mr. H. Middlehurst, Manchester Street; and Messrs. W. Rowlands & Sons, West Derby. The usual loyal toasts having been duly honoured a capital musical programme was enjoyed. A vote of thanks to the artistes was suitably proposed by Mr. R. W. Ker, and a similar vote to the Chairman by Mr. A. G. Davies. It was admitted by all present to have been one of the most successful evenings ever held by members of the Association.—R. P. R.

— ROYAL METEOROLOGICAL SOCIETY.—The annual meeting of this Society was held on Wednesday evening, the 18th inst., at the Institute of Civil Engineers, Westminster, Mr. F. C. Bayard, L.L.M., President, in the chair. The Council, in their report, stated that owing to the premises now occupied by the Society at 22, Great George Street being required by the Government, they had been obliged to seek accommodation elsewhere, but not being able to secure offices in the immediate neighbourhood they had taken a suite of rooms at 70, Victoria Street. Mr. Bayard, in his presidential address, gave an account of the Government meteorological organisations in various parts of the world. He first briefly described the founding of each system, and mentioned the names of the various directors, and then enumerated the number of observing stations associated with each organisation. In most countries forecasts of the weather are issued, and Mr. Bayard gave some interesting particulars as to the success attained by each office. The amount of money voted by the various governments for the support of meteorology showed what a very small portion of the revenue of the different countries goes towards the promotion of this science. In the British Isles it is 2s. 6d. per square mile, but only about one-third of a farthing per head. The address was illustrated by a large number of lantern slides, showing views of the various observatories and portraits of the directors. Mr. Bayard was re-elected President for the ensuing year.

— THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—I have pleasure in announcing that the late Mr. John Lee has left the Institution a legacy of £100, free of legacy duty.—GEORGE J. INGRAM, Secretary.

— GARDENING APPOINTMENTS.—Mr. A. Young, who for nearly five years has been head gardener to the Earl of Cork, Marston, Frome, has been engaged by Sir J. Heathcote Amory, Bart., Knightshayes Court, Tiverton, Devon, in a similar capacity, and enters his duties there on February 9th next. Mr. G. D. Chisholm, for the last six years gardener to Major Middleton, Acacia, Roundhay, Leeds, has been appointed gardener to Mrs. Illingworth, Thornton-le-Street, Thirsk, Yorkshire.

— ARSENIC AND VEGETATION.—In connection with the modern use of arsenical insecticides it is important to take note of such researches as have been made by Herr J. Stokless. He has ascertained that both arsenious and arsenic acids are highly poisonous to the bulk of plants. He finds no truth in the assertion that arsenic may be drawn into vegetable tissues with advantage and serve the purpose of phosphorus. On the other hand, compounds containing iron are very important; they help in the growth of young organs, stimulating the formation of cells.—J. R. S. C.

— A LOST CHORD.—If there is no blight on Mr. Fenn's plants there is assuredly none about himself when he can still pen an article so breezy as his latest, and, I fondly hope, not his last, in the Journal. I wonder if his favourite anti-blight has anything to do with his own wonderful vitality. Does he give himself a dusting occasionally by way of a preventive against human ailments? One who would like to meet him sends him a hearty greeting which, it is hoped, he will accept, even if it comes from one guilty of "long drawn out phrases," in contrast with the brevity of the veteran.—S.

— THE DEVELOPMENT OF THE WEST INDIES.—With a view to relieving the depression in the West Indies, Mr. Chamberlain has been promoting a scheme for the development of fruit cultivation and exportation for the English market. The climate of the islands is admirably suited for the growing of Bananas, Pine Apples, Oranges, and other tropical fruits, and a large trade in these fruits has grown up of recent years with the United States. It is thought that by the establishment of a quick service of steamers under a Government subsidy large quantities of these fruits might be placed on the English market at prices which would render them within the reach of the poorest. With this object Mr. Chamberlain has been in communication with Messrs. Elder, Dempster and Co. of Liverpool and London, who propose to establish a fortnightly service of steamers to and from Liverpool, the voyage to occupy about thirteen days. It is intended, also, to develop the islands as a health resort.

— GRAND YORKSHIRE GALA.—The annual meeting of the life members and guarantors of the Grand Yorkshire Gala was held recently at Harker's Hotel, Sir Christopher Milward presiding. In the course of his introductory address the Chairman said he had to congratulate them on one of the most successful years experienced in the history of the Grand Yorkshire Gala. Proceeding, Sir Christopher proposed the election of the Lord Mayor as President for the ensuing year. Since the establishment of the Gala they had had the honour of the co-operation both of the Lord Mayor and Sheriff, but it was seldom that they were able to elect to the presidency one so closely associated with the management of the Gala as the present Lord Mayor, who had served them as vice-chairman. The motion, seconded by Mr. Alderman Foster, was carried by acclamation. The re-election of Sir Christopher Milward as Chairman of the Council was moved by the Lord Mayor, who referred to the excellent manner in which Sir Christopher had discharged the duties, adding that there was no member of the Council so capable of filling the position, or who possessed such a thorough knowledge of the working of the various Committees. The Sheriff, in seconding the nomination, hoped he would live long to serve them in that position. The resolution was adopted unanimously. The Chairman appropriately acknowledged his re-election. Mr. Joseph Wilkinson was unanimously re-elected Treasurer, Mr. C. W. Simmons Secretary, and Messrs. Pearson and Taylor Auditors. Mr. T. G. Hodgson proposed that the sum of £650 be granted to the Floral Committee. The amount was the same as that granted last year, but he understood that the Committee contemplated a revision of the schedule, which was not up to date. The sum of £230 was granted for the musical arrangements, £120 for the firework displays, £60 for balloon ascents, and £175 for the entertainments. Mr. Hugh Low, of the firm of Messrs. Hugh Low & Co., London, was elected a life member.

— **THE DEEP ROOTING OF ONIONS.**—In reading "Cassell's Popular Gardening" on the culture of Onions, I find it is stated that ample means have been afforded for testing that Onion roots have penetrated to the depth of 6 feet. I shall be glad to have as much information on the subject as any readers can obligingly give me. —**ANXIOUS TO LEARN.**

— **LA SEMAINE HORTICOLE.**—With the issue, dated January 7th, our Belgian contemporary commences a new stage of existence with an extended title and a broader base of operations. Hitherto it has been in the hands of Mons. Lucien Linden, but has now passed to a company, whose endeavour will be to materially increase its utility to continental horticulturists. We hope the promised efforts will be crowned by success. The full title of the periodical will be "La Semaine Horticole et Revue des Culture Coloniales."

— **CHESTER PANTON SOCIETY.**—The first lecture for the present session was delivered in the Grosvenor Museum on Saturday evening last by Mr. E. Stubbs, gardener to Mrs. Hudson, Bache Hall, who took for his subject "Chrysanthemums." In the absence of the President, the chair was occupied by Mr. J. Jackson, Capenhurst. Mr. Stubbs has for some years been recognised as one of the champion growers in the district, having several times carried off premier honours for Chrysanthemums at the Society's annual exhibition. It was mainly from an exhibitor's point of view that Mr. Stubbs dealt with his subject, and in the course of his remarks he explained exactly his methods of culture, and gave valuable hints, which were much appreciated by other growers who were present. An interesting discussion followed, and at the close a hearty vote of thanks was accorded to the essayist for his very practical paper.

— **THE FATE OF CROHAM HURST.**—On a recent morning, under the auspices of the Selborne Society, a demonstration was held on the summit of Croham Hurst to protest against the site being permitted to fall into the hands of the builders, and to urge its acquisition by the town of Croydon. Croham Hurst is a finely wooded elevation in the southern suburbs of Croydon, whence very extensive views of the surrounding country may be obtained, and which, next to the Shirley Hills, is probably the most favourite place of resort in the spring and summer time with the inhabitants. The land belongs to the Whitgift Trust. Of late rumours have been current in the town that there was a probability of that portion of the estate which borders on the hillside being laid out for building purposes, and, it being felt by some of the townspeople that the erection of houses in the immediate vicinity of the Hurst was highly objectionable, the meeting was called to denounce the proposal. The Chairman was Mr. E. A. Martin, the Hon. Secretary of the Selborne Society. A resolution was passed calling upon the Corporation to take steps to secure Croham Hurst in perpetuity for the use of the inhabitants of Croydon, and strongly deprecating any building operations in the locality.—("Daily Chronicle.")

— **WILD BIRDS IN LONDON.**—There is a variety of bird-life native to London far greater than most people, we fancy, are aware. A walk in any of our larger parks, especially in the neighbourhood of the lakes, or upon Hampstead Heath, will reveal it to us. Many of the waterfowl on our ornamental waters are wild. The Parks Committee of the County Council stocks its lakes and islands with fowl, but many wild ducks and other species of water birds come in addition to these. The kingfisher, too, is a frequent visitor, and actually breeds in London. The cuckoo and the magpie will be noted; but the latter, because of the mischief it does, is not too heartily welcomed by the park authorities. Hampstead Heath is the favourite London resort of the goldfinches; while their relatives, the greenfinches, favour St. James's Park, and the bullfinch and chaffinch are seen in several town quarters. The linnets, unfortunately, are leaving us, and the larks have already left. Their desertion of town is chiefly a matter of suitable food. The tomtit, most amusing of small birds, was retained in Battersea Park by Mr. Sexby, the chief of the Parks Department, who adopted the device of hanging little pieces of fat on the trees. Then, too, we have blackbirds—there was a white specimen haunting our parks a year or two ago—rooks, jackdaws, most solemn of all birds, wagtails, with their curious dipping flight, and of course the robins, wrens, starlings, and wood pigeons. The worst enemy of the London bird is, unfortunately, one against whom Acts of Parliament afford very little protection. He has no proper respect for the law. If it were not for the prowling cat bird life in London would probably be even more varied and plentiful than it is. There are enormous numbers of stray cats in town; and the parks are a happy hunting ground for them. Mr. Sexby reports that in Finsbury Park, where the waterfowl are located on the island, cats will take to the water and swim across to get at their prey.

— **"GARDENING FOR ALL."**—A copy of the second edition of the useful little book, "Gardening for All," has been sent to Her Majesty the Queen by the author, Mr. James Udale, F.R.H.S., Droitwich, the chief gardening instructor for Worcestershire. The copy sent to Her Majesty has been graciously accepted and acknowledged by Lord Edward Pelham-Clinton.

— **FRENCH BEAN SYON HOUSE.**—This proved one of the most prolific varieties cultivated in pots for main crops indoors last year. The plant possesses a good constitution, does not grow so tall as some, and the pods, which are most freely produced, are of good size. Until last season the variety to me was known only by name, but so favourable was the impression made under its first trial, that it will in future claim the notice which its merits deserve, and I strongly recommend it to the notice of others, to whom it may be, except in name, a stranger.—W. S.

— **PEAR PRESIDENT BARABE.**—When at Gunton Park in August I noted this Pear growing against a south wall, where it was carrying a full crop of shapely hardy looking fruit. I have to-day, January 10th, had an opportunity of testing its quality. It is of buttery texture, sweet and juicy, and of a pleasing flavour. For use in January President Barabe ought to be valuable too, as really good Pears are then scarce. As a cordon on the Quince stock planted in a warm situation this year should prove a success.—E. M.

— **SUMMARY OF METEOROLOGICAL OBSERVATIONS, 1898.**—This has been the driest year since 1887, and has only been exceeded twice since 1876—viz., 1884, total rainfall 18.31 inches; and 1887, total rainfall 19.46 inches; and it has been the warmest year since 1893, with sunshine much above the average. The prevailing direction of the wind was W. on 116 days. The total rainfall was 19.63 inches, which fell on 160 days, and is 7.16 inches below the average for the year. The greatest daily fall was 0.96 inch, on August 6th. Barometer (corrected and reduced), highest reading 30.629 inches, on January 15th, at 9 P.M.; lowest reading 28.795 inches, on November 25th, at 9 A.M. Thermometers, highest in the shade 88°, on September 8th; lowest 20°, on February 21st. Mean of daily maxima, 56.75°; mean of daily minima, 41.53°. Mean temperature of the year, 49.14°; lowest on the grass 13°, on February 21st; highest in the sun 150°, on September 8th. Mean temperature of the earth at 3 feet, 49.84°. Total sunshine 1581 hours 20 min. There were sixty sunless days.—H. H. DIVERS, *Belvoir Castle Gardens, Grantham.*

— **BOHEMIAN FORESTS.**—Bohemia is one of the most populous countries in the world; its climate is relatively cool with rather severe winters, and therefore much fuel is used, which is largely taken from the forests covering the mountain sides. Yet after the many centuries during which these forests have furnished fuel and building material for a dense population, they retain nearly their original area. This, says Consul Mahin, is due to the forethought of the Government in ordaining that as trees were cut down others should be planted to fill the vacancies. Vast stretches of dense forests cover the mountain slopes; the wood is mostly pine. Trees are constantly being cut, but wherever a clearing is made small trees are planted the next spring. What at a distance may appear to be a bare spot in the forest, on a nearer view is found to be covered with little trees set out in symmetrical rows, and varying in height according to the length of time since they were planted. The new trees are raised from the seed in small enclosures scattered in the mountains, and are thence transplanted.—("Journal of the Society of Arts.")

— **A PLAGUE OF LOCUSTS AT KIMBERLEY.**—A correspondent, under date of November 17th, 1898, writes to a contemporary:—"Locusts have been with us since Monday, and for four days a continuous unbroken stream of little brown insects, a little larger than a bee, with legs like grasshoppers, have been hop, hop, hopping past my door. They show as yet absolutely no sign of diminishing in numbers. They go steadily on, and all in the same direction—north. The streets running east and west are comparatively free from them—a few millions certainly do divert their course into them for a little, but merely, it would appear, to have a brief rest before rejoining the maddening throng to hop on, and on, and on—whither? If we leave our gate open they sweep into our garden, in which is a tree I wanted to save. I have bathed it in tar, in paraffin, in disinfectant—they all appear to whet their appetites. It takes money, patience, and trouble to make a respectable garden in this place, and now the locusts, just at the beginning of the summer, will eat up everything. It would be comic were it not for the pathos of it, to see women spending their days in brush, brush, brushing, with as hopeless a task before them as the great Mrs. Partington, at the inflowing sea of locusts, trying to protect their gardens from the rising tide. There is a ditch round the public gardens, and fires are burned in it, into which the locusts walk in millions."

ARCHIE RAY.

THOUGH the Chrysanthemum fever has long passed its highest point for another season it will not be out of place to give another photograph reproduction of an English sport. This (fig. 14) represents Archie Ray, which visitors to the National Chrysanthemum Society's meeting in November will remember was so excellently shown. The variety is a sport from the well-known Mdle. M. A. de Galbert, and is of exceptional promise. The flowers are primrose yellow in colour, and have long broad incurving florets in the centre with recurving outer florets, and partake largely of the character of the parent, but have also a striking resemblance to the chastely beautiful Mdle. Thérèse Rey. The habit of the plant leaves little to be desired, and it is said that good flowers can be secured from any bud. This sport originated with Messrs. W. Ray & Co., Mount Pleasant Nurseries, Teynham, Kent, in 1896; it is now quite fixed, and should become popular both for general purposes as well as for exhibition.

"LE CHRYSANTHEME."

As was the case last year, the December number of the French N.C.S. Journal is an unusually bulky one. The list of new members brings the total up to over 500, an achievement of no little importance, considering the Society is as yet only a young one. Among the various items of interest may be mentioned the concluding portion of M. Salète's report of his visit to the Aquarium Show last November. There are also reports of shows at Troyes, Algiers, Cette, Nîmes, Langres, Grenoble, Geneva, and other places. The third Conference and Exhibition, held under the auspices of the Society, are fully dealt with; the papers and discussions on the various subjects of interest that were treated occupying a large portion of the number. A statement of receipts and payments for the past year shows a balance in hand of nearly £50.—P.

NATIONAL CHRYSANTHEMUM SOCIETY.

CLASSIFICATION OF VARIETIES.

SOCIETIES in affiliation with the N.C.S. are desired to print the following lists in their schedules of prizes as binding upon exhibitors, and thus relieve both judges and committees of much vexation arising from disputes as to the distinctness or otherwise of certain popular varieties much exhibited. It will be understood that in the case of societies which may not be desirous of coming under the operation of these lists, and not printing them in their schedules, that they are not binding upon the exhibitors at such societies' shows; but it is earnestly desired that all affiliated societies may adopt them, and make them obligatory upon their exhibitors.

The following list of varieties which have been distributed since the publication of the Jubilee edition of the Society's official catalogue in 1896 are classed as—

INCURVED VARIETIES.

Ada Owen	Miss Phyllis Fowler
Austin Cannell	Miss Violet Foster
Baronne de Veillard	Mrs. Airdrie
C. S. Bates	Mrs. Col. Goodyear
Chrysanthémiste Bruant	Mrs. F. Hepper
Dome d'Or	Mrs. Gerald Williams
Duchess of Fife	Mrs. H. J. Jones
Ernest Cannell	Mrs. James Eadie
General Maurie	Mrs. N. Molyneux
Golden Gem	Mrs. Sarah Owen
Golden Nugget	Mrs. W. Howe
Hanwell Glory	Mr. J. Kearns
Harold Wells	Mr. James Murray
Ialine	Mr. M. Russell
Ideality	Mons. Desblanc
John Miles	Owen's Crimson
King of Orange	Pearl Palace
Lady Isabel	Percy Surman
L'Améthiste	Perle Dauphinoise
Le Marcadeon	R. D. Douglas
Leonard Payne	Rena Dula
Lyne Junior	Rose Owen
Ma Perfection	Sir Trevor Lawrence
Madame Edmond Roger	The Egyptian
Madame Ferlat	Thomas Singleton
Mdle. Lucie Faure	Topaze Orientale
Miss Annie Hill	Triomphe d'Eve
Miss Dorothy Foster	W. Carpenter
Miss Godsmarek	Yvonne Desblanc
Miss Louise D. Blac	

The following are classed as—

JAPANESE INCURVED.

Duke of Wellington

President Nonin

Swanley Giant

SYNONYMOUS, OR TOO-MUCH-ALIKE VARIETIES.

The following is a list of varieties of Chrysanthemums, either classed as synonymous, or as too-much-alike, or which at times so nearly approach each other in general appearance that they *must* not be shown on the same stand.

INCURVED VARIETIES.

C. H. Curtis	John Salter
Major Bouaffon	Mr. Howe
Duchess of Fife	Lady Dorothy
Mrs. Airdrie	Charles Gibson
Empress of India	Lord Alcester
Lady H. St. Clair	Princess Imperial
Mrs. Cunningham	Miss M. A. Haggas
Snowball	Richard Parker
White Queen	Mrs. George Rundie
Golden Empress of India	Mrs. George Parnell
Bruce Findlay	Mrs. W. C. Egan
Golden George Glenney	Countess of Warwick
Mrs. Dixon	Princess of Teck
Mrs. C. H. Glover	Charles Shoesmith
John Doughty	Christmas Number
Mrs. Robert Mudie	Princess of Wales
Bronze Queen of England	Beauty of St. John's Wood
John Lambert	Mrs. Heale
Golden Queen of England	White Princess
Emily Dale	Queen of England
Emily Dale Improved	Blush Queen of England

JAPANESE VARIETIES.

Australie	Pride of Madford
Mr. T. Carrington	Beauty of Teignmouth
G. J. Warren	Sunflower
Yellow Madame Carnot	Swanley Yellow
Madame Louis Remy	W. Slogrove
Lady Ellen Clarke	Improved W. H. Lincoln
Mrs. C. Blick	T. Selwood
Mrs. Richard Jones	

HAIRY VARIETIES.

Enfant des deux Mondes	Hairy Wonder	Esau
White Louis Boehmer	R. M. Gray	Princess Eua

The attention of exhibitors is particularly called to the foregoing list of too-much-alike varieties bracketed together, which should be carefully examined previous to staging blooms for competition.—RICHARD DEAN, V.M.H., *Secretary*.

FRENCH CERTIFICATED CHRYSANTHEMUMS.

AT the recent Paris show there was a large number of novelties certificated, more perhaps than it would be useful to mention here. The principal exhibitors to whom these awards were made were MM. Delaux, Nonin, Ragout, W. Wells, Debrié, Chantrier, Rémy, Langlois, Scalarandis, Calvat, and De Reydellet. This show, it will be remembered, is held by the National Horticultural Society of France. The French N.C.S. has held several meetings of its Floral Committee, and a goodly number of these distinctions have been awarded, the principal exhibitors being MM. Bonnefous, Calvat, De Reydellet, Rozain, Bouchardat, Delaux, Chantrier, Delvert, Nonin, Scalarandis, Boric, Charmet, and Poncet. The show at Lille was also the occasion of awarding a large number of certificates, the following growers being successful at this northern show:—MM. Calvat, Wells, Cordonnier, De Reydellet, Mulnard, Chantrier, and Bonnefous.—C.

CHRYSANTHEMUMS IN THE NORTH OF FRANCE.

It was in the north of France that big bloom culture first made known the merits of the Chrysanthemum as an exhibition flower to the French public, and the recent show at Lille has no doubt given a further impetus to its cultivation. The "Nord Horticole," a bright and interesting little monthly, largely devoted to Chrysanthemum matters, and the official organ of the Northern French Chrysanthemum Society, contains a lengthy account of the Lille Exhibition in November last, and is illustrated with ten interesting photographic reproductions of exhibits and views. There is also a translation of an article on the rust and other matter appropriate to the season.—P.

THE N.C.S. MEDAL AWARDS.

In the report of the past year's work of the Royal Horticultural Society I observe, in relation to the vexed medal award question, the Council suggests, though in veiled terms, that trade groups at the Drill Hall should not be too readily awarded medals. I do not assume

Practically it is difficult to prevent trade growers from exhibiting produce grown by others for them. Nothing is more common than for traders who have special stocks of their own to pay other persons to grow the same for them, seeing that it is often practicable for others to present them in superior form. Were these things exhibited

FIG. 14.—ARCHIE RAY.

that the Executive of the N.C.S. would be likely to follow the lead of the R.H.S. in this matter; but were it the rule that no awards of medals be made to such groups in either case there would be no room for the grumbling of which I have complained as disfiguring several Chrysanthemum trade lists.

for prizes as actually grown by the exhibitor it would be immoral, but when simply presented as examples of varieties or stocks produced under the best culture no one can complain. Of course, if in such case anyone were to publish that all these exhibits "were grown by us personally, and in our own establishments," that would be false.

No honourable trader, however, does that. The real evil lies in the practice on the part of executives in making such very questionable awards as medals to trade exhibits at all, especially when it is found they form the ground of assertion in catalogues that give pain to many readers.

I have a new list and a long letter in from one trader. I see in the list that he again refers to this disagreement with the action of the N.C.S.; and whilst I again condemn the introduction of any personal quarrel into a trade list, I can but say that every word found in the complaint justifies my advice to wash hands entirely of any association that breeds so much of ill feeling and dissatisfaction. The popularity of the Chrysanthemum and its culture does not depend on a show or two at the Royal Aquarium. There are very many others not less worthy of consideration.

I observe that the esteemed Chairman of the N.C.S. Executive retires from the office. How soon these officials have enough of it! And no wonder, when what should be a real National Society is controlled, not more in the interests of the Chrysanthemum than that of an entertainment company.—A. D.

CHRYSANTHEMUM EXHIBITS AND MEDALS.

It was not my intention to enter the controversy initiated by "A. D.," who apparently is one of those who consider themselves critics on all subjects. Surely it is a little presumptuous of "A. D.," or anyone, to say what should or should not appear in a catalogue. We may next expect to be told how many varieties we may catalogue, and those only of certain raisers, what colour its cover may be, and so on. I have always understood that catalogues were the property of the firms who published them. May I suggest to "A. D.," that he should use his pen against "cliquism" and jobbery wherever they may exist, he would then be doing horticulture a service. Personally, I must admit that what I wrote in compiling my catalogue was much against my inclination, for I knew there would be some who would consider "trade jealousy" was at the bottom of it all, but the circumstances of the case left no other course open to me, and I said as little as I could.

"A. D." now suggests that the proper course for Chrysanthemum traders who object to certain proceedings is for them to "wash their hands of a body that acts contrary to their desires, or, failing that, to bring forward complaints and objections at committee meetings." The first proposition is presumably what a certain section might desire, and I can hardly believe that "A. D." has joined this party. As to the second proposition, it has been tried and found useless. Letters may be written and explanations asked for, but at the meeting someone is quick to suggest that the letter lie on the table, and so the complaint is "snuffed out." Other letters, I am credibly informed, are never placed before the Committee. Will "A. D." take the trouble to inquire why the genial and straightforward Chairman of the N.C.S. has intimated his intention of resigning the position that he occupies so creditably? But we will suppose that our complaints are attended to, and explanations are tendered; of what service are they unless they are given the same amount of publicity as are the circumstances of which we complain?

I do not imagine that anyone values the various medals primarily for their intrinsic worth. I am sure I do not, but it is the value that the medals are supposed to give the exhibits that is aimed at. I have known a medal awarded to an exhibit of Chrysanthemums not a bloom of which was grown by the exhibitor. Much more could be said on this matter. I would, however, like to add that Chrysanthemum specialists are not alone in winning medals in this way, for I could mention a firm which exhibits at important shows collections of Carnation plants which are sent from the Channel Isles direct to the shows at which they are awarded medals.—W. J. GODFREY.

[We do not know what our correspondent has said in his catalogue, but he is entitled to say what he likes. Most business men know, or are not long in finding out, what best suits their purpose to publish. The rules and regulations of all societies are not alike. In certain classes the prizes are given for the products and skill in arranging them for making a great spectacular display, and not to the growers of the materials employed. An exhibitor is not open to reproach when he acts within the rules; and in clear cases of infringement formal protests, entered in precise form and within the stipulated time, receive in all societies with which we have been officially connected the careful attention of the committee. We have received more complaints relative to the awarding of prizes at the N.C.S. shows than from exhibitors at all other shows in the kingdom, but as the rules and regulations of the N.C.S. are neither sent to us officially nor by the complainants we have no opportunity for testing the merits of the several allegations. Catalogue statements are in their very nature *ex parte*, and there is an alternative side to every question in dispute. We are not prepared to admit that the Committee of the N.C.S. would sanction a proved case of injustice as against any exhibitor. If such outrages should be permitted by any society it would speedily be on the down grade in a dodgery hating country.]

ROYAL HORTICULTURAL SOCIETY.

THE COMMITTEES FOR 1899.

FULL particulars of the exhibitions of the Society can be had from the "Arrangements for 1899," in which are also given lists of the various committees, and these we reprint for the benefit of our readers.

SCIENTIFIC COMMITTEE.

Chairman.—Sir J. D. Hooker, K.C.S.I., C.B., F.R.S., V.M.H., Sunningdale.
Vice-Chairmen.—Dyer, Sir W. T. Thiselton, K.C.M.G., F.R.S., Royal Gardens, Kew.

Foster, Prof. M., V.M.H., Sec. R.S., Great Shelford, Cambridge.
Masters, Maxwell T., M.D., F.R.S., &c., Mount Avenue, Ealing, W.

Hon. Secretary.—Rev. Prof. G. Henslow, M.A., V.M.H., F.L.S., 80, Holland Park, W.

Allen J., Park House, Shepton Mallet.

Baker, J. G., F.R.S., Royal Gardens, Kew.

Balfour, Prof. I. B., F.R.S., V.M.H., Botanic Gardens, Edinburgh.

Bonavia, Dr. E., Westwood, Richmond Road, Worthing.

Burbidge, F. W., M.A., V.M.H., Trinity College Gardens, Dublin.

Church, Prof. A. H., M.A., F.R.S., Shelsley, Kew Gardens.

Darwin, Francis, F.R.S., Wychfield, Huntingdon Road, Cambridge.

Dod, Rev. C. Wolley, M.A., V.M.H., Edge Hall, Malpas, Cheshire.

Elwes, H. J., F.L.S., V.M.H., Colesborne, Andoversford, Glus.

Engleheart, Rev. G. H., M.A., Appleshaw, Andover.

Farmer, Prof. J. B., M.A., Royal College of Science, S. Kensington.

Frankland, E., F.R.S., The Yews, Reigate Hill, Reigate.

Godman, F. Du Cane, F.R.S., 10, Chandos Street, Cavendish Square.

Im Thurn, E. F., Gov. Admin., N.W. District, British Guiana.

Lindsay, R., Botanic Gardens, Edinburgh.

Llewelyn, Sir J. T. D., Bart, F.L.S., Penllergaer, Swansea.

Lynch, R. Irwin, A.L.S., Botanic Gardens, Cambridge.

Maxwell, W. H., Munches, Dalbeattie, N.B.

McLachlan, R., F.R.S., Westview, Clarendon Road, Lewisham, S.E.

Michael, A. D., F.L.S., Cadogan Mansions, Sloane Square, S.W.

Morris, D., C.M.G., M.A., F.L.S., D.Sc., Imp. Agri. Dept., Barbados.

Müller, Hugo, Ph.D., F.R.S., 13, Park Square East, Regent's Park.

Oliver, F. W., D.Sc., F.L.S., 2, The Vale, Chelsea, S.W.

Plowright, C. B., F.L.S., 7, King Street, King's Lynn.

Russell, W. J., F.R.S., Ph.D., 34, Upper Hamilton Terrace, N.W.

Scott, D. H., M.A., Ph.D., F.R.S., F.L.S., The Old Palace, Richmond, S.W.

Sutton, A. W., V.M.H., F.L.S., Reading.

Veitch, H. J., F.L.S., King's Road, Chelsea, S.W.

Ward, Prof. Marshall, F.R.S., Botanical Laboratory, Cambridge.

Wilson, Geo. F., F.R.S., V.M.H., Heatherbank, Weybridge Heath.

FRUIT AND VEGETABLE COMMITTEE.

Chairman.—Crowley, Philip, F.L.S., Waddon House, Croydon.

Vice-Chairmen.—Balderson, H., Corner Hall, Hemel Hempstead.

Bunyard, Geo., V.M.H., The Royal Nurseries, Maidstone.

Rivers, T. Francis, V.M.H., Sawbridgeworth.

Secretary.—Wright, S. T., R.H.S. Gardens, Chiswick.

Barron, A. F., V.M.H., Sutton Court Road, Chiswick, W.

Basham, J., Fair Oak, Bursaleg, Newport, Mon.

Bates, W., Poulett Lodge Gardens, Twickenham.

Bennett, W., Rangemore Park Gardens, Burton-on-Trent.

Cheal, Joseph, Crawley, Sussex.

Crump, W., V.M.H., Madresfield Court Gardens, Malvern.

Dean, A., 62, Richmond Road, Kingston, S.W.

Divers, W. H., Belvoir Castle Gardens, Grantham.

Dunn, Malcolm, V.M.H., The Palace Gardens, Dalkeith, N.B.

Empson, W. J., Ampthill House Gardens, Beds.

Farr, W., Spring Grove House Gardens, Isleworth.

Fife, Robert, Dobbie's Nurseries, Orpington, Kent.

Gleeson, W., Warren House Gardens, Stanmore.

Herrin, C., Dropmore Gardens, Maidenhead.

Iggulden, W., North View, Frome, Somerset.

Lane, Fred. Q., Berkhamsted.

McIndoe, James, V.M.H., Hutton Hall Gardens, Guisborough.

Miles, G. T., Wycomb Abbey, High Wycomb.

Mortimer, S., Rowledge, Farnham, Surrey.

Norman, G., Hatfield House Gardens, Hatfield.

Parker, R., Goodwood, Chichester.

Pearson, A. H., The Nurseries, Chilwell, Notts.

Pope, W., Highclere Gardens, Newbury.

Poupart, W., Marsh Farm, Twickenham.

Reynolds, G., The Gardens, Gunnersbury Park, Acton.

Saltmarsh, T. J., The Nurseries, Chelmsford.

Shaw-Baker, Dr. E., The Cedars, East Grinstead.

Smith, James, V.M.H., The Gardens, Mentmore, Leighton Buzzard.

Veitch, J. H., King's Road, Chelsea.

Veitch, P. C. M., The Royal Nurseries, Exeter.

Wilks, Rev. W., M.A., Shirley Vicarage, Croydon.

Willard, Jesse, Holly Lodge Gardens, Highgate, N.

FLORAL COMMITTEE.

- Chairman.*—Marshall, William, Auchinraith, Bexley.
Vice-Chairmen.—Fraser, John, V.M.H., The Nurseries, South Woodford.
 Paul, George, V.M.H., The Old Nurseries, Cheshunt.
Secretary.—T. Humphreys, R.H.S. Gardens, Chiswick, W.
 Bain, W., The Gardens, Burford Lodge, Dorking.
 Barnes, N. F., Eaton Gardens, Chester.
 Barr, W., 12, King Street, Covent Garden, W.C.
 Beckett, E., Aldenham House Gardens, Elstree.
 Blick, Chas., The Warren, Hayes Common, Beckenham.
 Cook, E. T., 9, Fairlawn Grove, Chiswick.
 Crane, D. B., 4, Woodview Terrace, Archway Road, Highgate, N.
 Cutbush, H. J., The Nurseries, Highgate, N.
 Dean, R., V.M.H., 42, Ranelagh Road, Ealing, W.
 Drury, C. T., F.L.S., V.M.H., 25, Windsor Road, Forest Gate.
 Fielder, L. R., St. James, West Malvern.
 Fitt, J. H., The Frythe Gardens, Welwyn.
 Fraser, John, 4, Willow Cottages, Kew.
 Gordon, G., V.M.H., Endsleigh, Priory Park, Kew.
 Herbst, H., V.M.H., Stanmore, Kew Road, Richmond.
 Howe, W., Park Hill Gardens, Streatham Common.
 Jeffries, C., Boston House Gardens, Brentford.
 Jenkins, E. H., Queen's Road, Hampton Hill, Middlesex.
 Jennings, J., Ascott Gardens, Leighton Buzzard.
 Jones, H. J., Ryecroft, Hither Green, Lewisham.
 Ker, R. Wilson, Basnett Street, Liverpool.
 Laing, J., V.M.H., Forest Hill, S.E.
 Lowe, R. B., Ashridge Gardens, Berkhamsted.
 McLeod, J., Dover House Gardens, Roehampton.
 May, H. B., Dyson's Lane, Upper Edmonton.
 Mawley, E., Rosebank, Berkhamsted.

 Ware, Walter T., Inglecombe Nurseries, near Bath.
 Wilks, Rev. W., Shirley Vicarage, Croydon.
 Willmott, Miss, V.M.H., Warley Place, Great Warley, Essex.

The Narcissus Committee will meet in the Drill Hall, James Street, Victoria Street, Westminster, on the following dates, at twelve o'clock noon—viz., March 14th, 28th, April 18th, and May 2nd, 1899.

SWEET PEAS.

SWEET PEAS are now most highly appreciated in the flower garden. I can well remember twenty-five years ago hearing the cottagers talk a lot about their "Posy Peas." These were short-stemmed, small-leaved, and small-flowered varieties, about 3 feet high, and the flowers were mostly dark purple. What a contrast to those of to-day. Last year our Peas ran 7 to 9 feet high, fell over the stakes, and grew up. There were such stems and flowers—indeed, varieties like Prince Edward of York had stems 12 and 14 inches long, with four flowers on each stem, great giants, and yet charmingly graceful.

To secure the best results with Sweet Peas they should be sown in February, in 3 inch pots of good soil, with six seeds in a pot. Put the receptacles in a cool greenhouse or frame where there is slight warmth, and admit fresh air after germination has taken place, and when 2 inches high move the young plants to a cold frame and keep well aired preparatory to planting out outdoors when about 4 or 5 inches high. The ground should, if possible, have some shelter from high winds, but not be so shady as to draw them in any way. Add good manure to the garden soil, as it is impossible to get fine large flowers from plants grown on poor soil. Early in April, if the weather and ground be suitable, they should be transferred from the pots to the rows, planting each potful about 9 inches asunder in the rows, which should be 6 feet apart. This will give them room to develop, and the sooner stakes are placed the better, so as to afford a little shelter. Immediately flowering commences a good mulching of manure will help to extend the season and give larger flowers, but seed pods must not be allowed to remain on the plants.

The following are some of the best varieties selected when in bloom last July. Coquette is cream in colour, and has large flowers and foliage; Countess of Shrewsbury, with pale pink standards and white wings, is free and very charming; Duke of Sutherland is a fine dark; Mars has dark red flowers on long stems, and is valuable for cutting purposes; Prince of Wales, a bright rose self, has long stems carrying large flowers; Aurora and Mrs. J. Chamberlain are much alike, and have white striped and flaked with rose coloured flowers; Brilliant, a fine red, produces large flowers; while Blanche Burpee is the best white yet, although a new one, Sadce Burpee, is said to be superior; Countess of Aberdeen is a delicate pink and good, but rather prone to spot in wet weather; Crown Jewel is a delightful variety with long stems; and Celestial lavender blue. Other fine ones are Duke of Clarence, deep maroon, long stems, and large flowers; Emily Eckford, white with pink feathering; Gaiety, striped, should be grown in the smallest collections; Primrose, one of the best yellows; Katherine Tracey, a lovely pink which stands the wet weather better than Countess of Aberdeen; Little Dorritt, carmine, tinted pink with white wings and long stems; Lovely, a pink with long stems and large flowers; Prince Edward of York, satiny rose standards, pale wings, very long stems, large flowers, often four on a stem; Maid of Honour, with long stems and large white flowers edged with blue, distinct and good; Queen Victoria, primrose, long stems, large flowers, strong grower; Shahzada, deep maroon, very fine; Salopian, carmine, fine large flower on very long stems; Prima Donna, pink, large flowers, fine long stems; and Triumph, orange pink standards and white wings, a noble flower on long stalks.—S. J.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ANNUAL GENERAL MEETING.

The tone of the speakers at the annual meeting of the Gardeners' Royal Benevolent Institution meeting, held at Simpson's on Thursday last, was congratulatory throughout, as it well might be, considering the eminently satisfactory financial condition and the excellent manner in which the Society's affairs are conducted. As usual, Mr. Harry J. Veitch was the presiding genius, and he was supported by the Rev. W. Wilks, Dr. Maxwell T. Masters, and Messrs. G. Monro and Ranger Johnson. In addition to these, we observed Messrs. J. H. Veitch, J. Fraser, J. Hudson, R. Dean, A. Outram, W. Roupell, T. Peed, Jesse Willard, and J. H. White. After the usual formal business, the Chairman called upon the Secretary to read the report and balance sheet, which are appended.

REPORT OF COMMITTEE FOR 1898.

In presenting their annual report for the year 1898 the Committee of the Gardeners' Royal Benevolent Institution have much satisfaction in being able again to congratulate the members and subscribers on the prosperous condition of the Institution, its continued success, and the increased benefits it has been the means of conferring on a large number of old and worthy people who have been compelled to seek its assistance. At the commencement of the year 1898 there were 163 pensioners on the funds—ninety-three men and seventy-five widows, entailing an annual liability for annuities of £3060.

During the year sixteen of these have died, five of the men leaving widows, whose applications for a continuance of the pension have been carefully considered by the Committee, and their cases having been found to be in every way satisfactory and deserving they have been placed on the funds at £16 a year for life under Rule iii. 13. Their several names and ages are as follows:—1, Jane Warr, widow of Silas Warr, North Cadbury, Bath, aged seventy-one; 2, Mary Wady, widow of Michael Wady, Bakers Lane, Streatham, aged sixty-nine; 3, Euphemia Lowe, widow of Peter Lowe, Cambray, Cheltenham, aged seventy; 4, Phoebe Coleman, widow of W. Coleman, Southborough, Kent, aged eighty-one; 5, Frances A. Holmes, widow of A. H. Holmes, Kyrle Road, Wandsworth Common, aged sixty-five.

Arrangements were made in the early part of the year for celebrating the annual festival dinner in aid of the funds in June, at which the Duke of Portland had undertaken to preside. Unfortunately, through ill-health, his Grace was unable to be present, but his place was filled by Sir Oswald Mosley, Bart., who occupied the chair in his Grace's stead. The Committee desire to place on record their deep indebtedness to Sir Oswald Mosley for his great kindness in coming forward to assist the Charity in the manner he did, and for his advocacy of its claims. They desire also to express their gratitude to the Duke of Portland for very kindly promising to preside at the festival on a future occasion. The Committee would take this opportunity of tendering their sincere thanks to those friends who rendered assistance as stewards, to those who sent flowers or fruit, and to all who in any way contributed to the success of the dinner.

The Committee further desire to offer their grateful thanks to supporters in various parts of the country who have been instrumental in arranging concerts, flower stalls, the opening of gardens, &c., in aid of the Institution. They would specially tender their sincere thanks to the hon. secretaries of the several auxiliaries for the valuable services they have rendered the Institution in its work. The Committee have to report that in consequence of the expiration of their tenancy in Parliament Street they were obliged to seek fresh offices. These were most difficult to obtain in the immediate neighbourhood, but they are glad to be able to announce that they have secured suitable and more prominent offices at 175, Victoria Street, Westminster, S.W., and they are hopeful that the new address will prove advantageous to the Charity in making it more widely known.

The Committee, after much deliberation, have decided to recommend an addition of seventeen pensioners to the list—five by resolution under Rule iii. 5, and twelve by votes in the usual way. This number is six over and above the vacancies which have occurred during the past year, and will make the total number of pensioners on the list 174. The Committee are fully aware of the increased liabilities they are incurring, but they feel confident that the majority of the friends of the Institution throughout the country will endorse their action in what may be termed a "forward policy"—viz., that of assisting a larger number of applicants than perhaps some may consider they are warranted in doing with their present average income.

The Committee are very pleased to inform the subscribers to the Victorian Era Fund that its operations during the past year—the first of its existence—have been greatly beneficial to the unsuccessful candidates who were formerly subscribers of the Institution, and who are awaiting election. The total amount disbursed from the fund was £106 10s., and was apportioned as follows: Andrew Bryan, subscriber thirteen years, £9 15s.; Francis Nixon, thirteen years, £9 15s.; James Plevy, twelve years, £9; George Staples, eleven years, £8 5s.; Caroline Woods, eleven years, £8 5s.; John Gibbons, ten years, £7 10s.; James Watt, ten years, £7 10s.; Elizabeth Hackwell, nine years, £6 15s.; George Wills, nine years, £6 15s.; Alfred Barnfield, eight years, £6; Annie Hatch, eight years, £6; Lucy Mitchell, seven years, £5 5s.; Joseph Shearn, seven years, £5 5s.; Alexander Lee, five years, £3 15s.; Thomas Evans, four years, £3; William Gould two years, £1 10s.; William Thomas, two years, £1 10s.; Emma Woodward, one year, 15s.; total, £106 10s.

The Committee would again point out that the interest derived from the fund is devoted exclusively for the benefit of those candidates who have been subscribers to the Institution. The amount raised for this fund was £4075, and the Committee are very anxious to bring up the total to £5000. To do this they require £925, and towards that sum they have received during the past year £540, whilst the following gentlemen have kindly promised £50 each conditionally on the amount being obtained:—N. Sherwood, Esq., Arthur W. Sutton, Esq., Leonard Sutton, Esq., and Harry J. Veitch, Esq. Thus they require but £185 to claim these promised gifts and complete the sum of £5000, and they are confident of being able to do this before the close of the present year.

In concluding their report the Committee, with feelings of deep regret, have to refer to the losses the Institution has sustained by the death of many valued friends and supporters during the past year, amongst whom they would specially mention the late Earl of Mansfield, a Vice-President of the Institution and an annual subscriber to its funds for fifty-two years; the late Sir Henry W. Peek, Bart., also a Vice-President and an annual subscriber for thirty-two years; the late Baron Ferdinand de Rothschild, who for many years was a generous contributor to the funds, and who occupied the chair at the anniversary festival in 1887; also the late Lord Hillingdon for many years a supporter of the Charity; and the late Earl of Lathom, Chairman of the anniversary festival in 1896. The warm-hearted liberality and personal interest of these many friends will be sorely missed, and the Committee earnestly appeal for new friends and supporters to take the places of those who for many years nobly helped the Gardeners' Royal Benevolent Institution to succour those who in their old age and adverse circumstances have been obliged to seek its aid.

THOS. MANNING, }
THOS. SWIFT, } Auditors.
JESSE WILLARD, }

So complete, said Mr. Veitch, in moving the adoption of the report and balance sheet, were the details there given that little remained to be added. He desired, however, to emphasise one or two points, particularly the fact that the expenses generally, had, during the year just closed, been less than in any previous year since the Society's foundation.

One item in the expenses he thought might not be thoroughly understood—viz., that of £31 0s. 6d. for brokerage, which was incurred through the death of Dr. Hogg and the retirement of Mr. John Lee, necessitating the transference of investments to the new trustees, B. Schröder, Esq., and the Hon. Walter Rothschild, M.P. He added that the broker had been generous enough to charge only half fees. It might, he continued, be considered a bold step on the part of the Committee to place six more persons on the Fund than had ever previously been the case, but there could be no standing still, there must be either progress or retrogression. To maintain this high standpoint, he observed, the Committee required more funds. Mr. Veitch adverted to the prolongation of life on the part of the pensioners, and thought it might be largely due to the benefits the Institution was able to confer upon them. With a brief word on other points, Mr. Veitch resumed his seat, and Mr. J. Hill White having come forward as seconder, the adoption of the report and balance sheet was carried unanimously.

The election of officers for the ensuing year was then proceeded with, and it is superfluous to say Mr. Veitch was unanimously re-elected, as also was Mr. G. J. Ingram, both of whom made a few remarks. Dr. Masters proposed, and Mr. J. Fraser seconded, that Messrs. J. Sexby, A. Watkins, W. Iceton, and G. Norman be placed on the Committee; and that Messrs. R. A. Milligan Hogg and J. Rochford be elected in place of Messrs. H. J. Cutbush and H. Williams, who retire by rotation. This was carried. Messrs. T. Manning, T. Swift, and J. Willard were re-elected auditors. Mr. W. Denning proposed that John Collins, Chas. Goodall, Wm. Kidd, Jonathan Squibbs, and Geo. Yearsley be placed on the funds without election, and this, with Mr. Melady as seconder, was carried.

Other purely formal business having been disposed of, the customary votes of thanks closed the meeting.

DECLARATION OF THE POLL.

The result of the poll was declared at 5.12 P.M. The candidates elected, and the number of votes polled by each, are appended: Joseph Sbearn, 4829; Alexander Lee, 4826; James Plevy, 4796; Emma Woodward, 4517; Sarah Ann Sims, 4159; Caroline Wood, 4134; Annie Hatch, 3938; Thomas Cawley, 3851; George Staples, 3829; George Cragg, 3825; Alfred Barnfield, 3719; John Akehurst, 3191. All those polling 3000 votes and upwards were elected. The totality of votes polled was about 92,000, and there were no fewer than 564 spoiled votes—a serious item.

A vote of thanks to the scrutineers of the ballot and to the Chairman concluded the business.

THE ANNUAL FRIENDLY SUPPER.

About seventy persons sat down to the annual supper, which was served in an adjoining room at six o'clock. Mr. George Monro occupied the chair. Amongst the notables present were the Rev. W. Wilks, and Messrs. H. J. Veitch, J. H. Veitch, N. N. Sherwood, H. B. May, H. J. Jones, G. Bunyard, Owen Thomas, Arnold Moss, E. J. Monro, T. Rochford, P. Kay, P. Crowley, J. Asshee, and C. Poupert.

The well-served repast having been discussed with right good will, and the customary loyal toasts honoured, the Chairman proceeded to give the toast of the evening—"Continued Success and Prosperity to Our Institution." In succinct fashion Mr. Monro sketched the progress and aims of the Institution since its inauguration in 1838. He drew particular attention to the fact that the gardening press had always given their doings the fullest publicity free of charge, only an infinitesimal amount being spent on advertising. In sixty years £30,000 had been distributed to the deserving poor gardeners and their widows, and the safety of all pensions had been fully guaranteed by the investment of moneys bearing interest. This could not have been done had they relied alone on the help received from gardeners. The Victorian Era Fund was alluded to, and Mr. Monro said that as the £5000 of the original scheme had now been all collected or promised with the exception of about £180 they might consider the Fund as completed; at any rate, he felt certain that it would be completed in the course of 1899. He urged upon gardeners to join the Society. Referring to the removal of the offices to 175, Victoria Street, he said that that very afternoon they had had evidence that prominence of offices was a good thing, for a gentleman had called and left £20 anonymously in memory of Robert Fortune. In concluding his earnest and sympathetic speech Mr. Monro coupled the toast with the name of Mr. H. J. Veitch.

In responding, Mr. Veitch met with quite an ovation. He congratulated the Institution on its continued prosperity and progress, and said that if a certain cheque had been sent in three days earlier than it was the year lately closed would have shown a bigger subscription list than any other. The pensions given to the aged and infirm had worked incalculable good, and in some cases it had undoubtedly been the means of lengthening the lives of the recipients, for one had lived to the mature age of 103, despite the fact that when he was seventy-two the doctor had averred that he could not live many months. Gratified at the success of the Victorian Era Fund, Mr. Veitch proposed the formation of a "Samaritan Fund," the interest of which should be employed to help the immediate wants of candidates for pensions who had not been subscribers to the Institution. About £2000 would suffice to found such a fund. He also would like to see some alterations in the system of voting, as he thought a subscription should carry the same number of votes each year. He was glad to be able to tell them that the Earl of Derby had consented to take the chair at the annual dinner on July 28th.

In giving the toast of "Our Country Friends," Mr. Owen Thomas spoke of how difficult and delicate was the persuading of eminent men to take the chair at the important meetings. The scope of the Institution

was greatly extended by the help they received from country friends, although he was sorry to say they got exceedingly little help from Scotland, Ireland, or Wales. Mr. J. Hill White of the Worcester auxiliary, whose name was coupled with the toast, replied.

Mr. N. N. Sherwood, in his usual happy way, proposed "Our Visitors." Mr. Jeffries, Mr. Bilney, and Mr. W. E. Brooks (who came in late) responded.

Mr. Arnold Moss reminded the audience of the favour Mr. Monro had done them in presiding that evening, and he also spoke of the quiet, unobtrusive, and yet effectual way in which he had worked for the "Benevolent." Mr. Monro acknowledged in a few well chosen words, and then proposed the health of their excellent Secretary, Mr. G. J. Ingram.

FIG. 15.—MEYENIA ERECTA.

Several donations were announced during the course of the evening, and included five guineas from Mr. Arnold Moss and £10 from Mr. Osman. Both Mr. H. J. Veitch and Mr. N. N. Sherwood promised their help for the "Samaritan Fund," and Mr. W. E. Brooks announced his intention of becoming a subscriber.

Numerous songs were given, and Mr. Poupert was a particular success in this direction, obtaining a most vociferous encore for the sweet old ballad "Mary." The cornet solos by Mr. E. J. Munro formed a pleasing addition, and were much appreciated.

MEYENIAS.

THE Meyenias, "Journeyman," constitute a small genus which is closely allied to the Thunbergias, although the former are by no means so well known as the latter. The cultural requirements of the Meyenias are few. If a light rich compost of fibrous loam, peat, leaf soil, and a small proportion of well-decayed manure be employed, and the plants grown in a brisk moist stove temperature, very little difficulty will be experienced in obtaining vigorous specimens that will flower satisfactorily. A position well exposed to light, and yet sufficiently shaded in hot sunny weather to prevent the foliage being scorched, or the colour of the flowers deteriorated, is beneficial, with abundant supplies of water to the roots and on the foliage while growth is active. The plants have sometimes a tendency to become rather straggling unless a little attention is given to pruning the too greatly extended or bare shoots: but this is a matter that is very easily accomplished. As regards increasing the stock, cuttings are readily obtained, and if judiciously selected usually strike readily in an ordinary propagating frame. The moderately firm wood should be chosen, as the tender extremities of the shoots are rather liable to damp.

One of the species of shrubby habit, *M. erecta*, is represented by the engraving (fig. 15). It is a handsome plant, with dark green leaves and trumpet-shaped flowers, the corollas of which have a pale yellow tube, a throat of a deeper yellow, and a rich purple limb. It is a really useful plant, as flowers are produced nearly all through the year, a quality which distinguishes it from the other forms.

THE ORPHAN FUND SECRETARYSHIP.

I HAVE incidentally learned that it is the intention of the Committee of the Orphan Fund (but I do not know whether by that term I am to understand the General Committee, or the sub-committee charged with the duty of selection from the many candidates), purpose presenting to the general meeting of subscribers next month one name only. That would look like an effort to rule the election and to overawe the general meeting, such as would receive and merit the strongest condemnation.

When a selection committee finds at their first meeting no less than twenty candidates worthy of reservation for future consideration, it is evident that there must be many eligible ones amongst them. If eventually that body should reduce the number to five no one would complain, provided irrespective of all personal or sectional partiality. If five be returned as eligible by the selection committee, that number should be placed before the general meeting for a final selection. That is the course taken by all public bodies, and should be as carefully followed in this case.

Most certainly, if it be attempted to gag the meeting at the outset by nominating one candidate only by the Committee with the childish threat—too utterly contemptible for one moment's consideration, that if the Committee's nominee be not elected that body will resign—such threat will be treated as it deserves, and the fullest effort will be made to secure a contest, that the subscribers present may return the candidate of their choice.

I want to warn subscribers in the country districts that unless they make a big effort and come up to attend the meeting, that those subscribers of the pure gardening element present will find themselves quite overborne by the market element which is to be whipped up to a man to vote for the market favourite candidate. Once let the Fund get controlled by that element, and true gardeners will withdraw from it wholesale. The Fund was originated in the interests of the gardener proper, and not in that of a wealthy market body. I have no doubt but that the general meeting will be a very large one, and far in excess of any that have preceded.

The gardening element have in the running several first-class candidates, each one of whom is worthy of confidence and support. The Fund is without doubt passing through a grave crisis, and its future, for prosperity or for failure, may absolutely depend on who the candidate may be that will on February 17th next be elected to the important office of Secretary.—A. D.

FUNGOID PESTS AND CHRYSANTHEMUM LEAF RUST.

ON Wednesday evening, January 18th, at the Guildhall, Exeter, an excellent programme of papers for the spring session of the Devon and Exeter Gardeners' Association was commenced. The essayist for the occasion was Mr. R. W. Hodder, gardener to Mrs. Trevor Barclay of Ponsonby, Torquay, and his subject was "The Fungi Pests of Our Gardens, with some Notes on Rust in Chrysanthemums." In the course of his paper Mr. Hodder submitted that fungi must be dealt with in the same way as the Convolvulus, which, if possible, should never be allowed to have a green leaf above ground. With regard to the fungus which caused the damping of seedlings, he said that all plantlets which seemed to be in any way affected should be removed at once, as well as the soil under them upon which the mycelium or spawn of the fungus was spreading. A drier atmosphere should be maintained where the pest attacked plants under glass.

Onion mildew or blight should be taken in hand immediately it made its appearance, and if the weather was at all favourable to mildew growth means should be adopted to prevent it. For both preventive and remedial purposes plants should be dusted with soot in the morning while the foliage was damp; if the foliage was not damp enough it should be sprinkled with a fine rose, so that the soot would adhere. Some growers recommended sulphide of potassium mixed into a paste with water, and applied to the parts affected. The best course to be adopted wherever the spot pest showed itself in Carnations was to stand the plants in an airy, light position, keeping them well on the dry side by giving no more water than was really necessary to prevent flagging, while the remedy which he had found the least detrimental to the grass of the Carnation was as follows:—Dissolve 3 lbs. of sulphate of copper in 1½ gallon of boiling water, then with the liquid slake half a bushel or as much more lime as necessary, so as to secure a fine powder, and then, with an ordinary puff, dust the foliage of the plants, allowing the powder to remain forty-eight hours, and then syringing and, if desirable, repeating the process. Another remedy was spraying the plants with a solution of sulphide of potassium, obtained by placing ½ oz. of sulphide in 5 gallons of water.

With regard to Potato disease, Mr. Hodder urged that on ground where a crop had grown, and there had been any appearance of the disease, everything that remained of the crop after the tubers had been removed should be burnt, and not allowed to remain upon the land, with opportunity thereby for the whole of the spores of the fungus to drop away from the decaying stalks into the soil to await another season, when perchance another Potato crop followed. He also suggested that tubers which were to form the sets of a future crop should be purified before being put into the soil by the application of some fungicide. The most effectual remedy yet applied for the disease itself seemed to be the Bordeaux mixture, or salts of copper in some form or other.

Dealing with "club root" or "fingers and toes" in Cabbages, Cauliflowers, Broccoli, and Turnips, he pointed out that it was difficult, in fact, almost impossible, to save plants in a clean state when once it got into the seed bed. Therefore, as soon as the pest was detected, the whole of the plants should be destroyed by fire, and a new plantation commenced upon a clean piece of land. Rotation of crops was an excellent way of preventing and getting rid of the disease. With regard to Tomato leaf blight and fruit rot, Mr. Hodder emphasised the great importance of cleanliness in culture and ventilation, and pointed out that if any fungicides of a poisonous nature were used it was absolutely necessary to be early. Affected fruit should be immediately picked and burned.

In his notes on rust in Chrysanthemums, Mr. Hodder dealt with the spots which now sometimes made their appearance on the under portions of leaves of the plant, described the various experiments he had made, and recommended the following as a remedy:—Boil 1 lb. of whale oil soap in half a gallon of water until dissolved, then add one gallon of best petroleum and keep on the boil for ten or fifteen minutes, stirring the whole time and obtaining a liquid about the consistency of gruel; then add of ammonia carbonate 2 or 3 ozs., and when cold place in jars for use as required in the proportion of one part of the emulsion to fifteen parts of water. The affected parts should be sprayed and resprayed every three or four weeks to flowering time. Fish manures should be avoided, but soot and clarified lime were suitable aids in repressing and preventing rust.

At the close of the paper there was an interesting discussion, and, on the motion of Mr. Slade, gardener at Poltimore House, who occupied the chair, Mr. Hodder was heartily thanked.—("Devon and Exeter Gazette.")

THE YOUNG GARDENERS' DOMAIN.

TOMATOES.

TOMATOES at present form one of the leading crops with the market grower, while in private gardens they are equally essential, so that a few notes on their culture will no doubt be beneficial to my fellow juniors. To obtain ripe fruit at the end of May or the beginning of June, the seeds should be sown forthwith, if the work has not already been done. Before sowing, place the compost in a house to become thoroughly warmed. It should consist of equal parts of good loam, leaf soil, and sand, well mixed. For sowing the seeds use 5 or 6-inch clean, well drained pots, filled to within half an inch from the top, and make the soil rather firm. Sow the seeds thinly, cover lightly, give a thorough watering, and place the pots on a shelf near the glass, allowing a temperature of 65°-70° night, 70°-75° day. When the plants are large enough to handle, pot them singly, and as deeply as possible in thumb pots. Apply water, and place the pots in a similar position to that the plants occupied as seedlings. When the roots reach the sides of the pots, the plants ought to be taken to a cooler house with a temperature of 55°-60° night, 60°-65° day.

As soon as they are well rooted, transfer them to clean, well drained, 6-inch pots, the compost consisting of two-thirds rough loam, and the remainder sweet horse droppings, with a little sand, and let the potting be both deep and firm. Place a neat stake to each, and give a thorough watering. Before the plants become root-bound, they should have their final shift. At this stage there are different methods of procedure, some growers utilising borders, while others grow them in pots, and the latter is perhaps preferable, for a better command can be had over the roots. For the final potting, clean, well-drained 12-inch pots are suitable, with a compost of two-thirds rough loam and a third of sweet horse droppings and old mortar rubble, with a slight sprinkling of Thomson's Vine manure and soot. Again let the potting be deep and firm, only filling the pots about one-half to permit future top-dressing. When the house has been thoroughly cleansed, the plants may be placed in their fruiting position, each having a stake for support until the trellis is reached. Keep the house at a temperature of 55°-60° night, 60°-65° day, with air, but avoid cold winds.

To insure a good crop, it will be found beneficial, when the plants are in bloom, to artificially aid fertilisation. When the first fruits are beginning to swell, a little weak liquid manure will be advantageous, and as time goes on and the plants gain vigour, it may be given rather stronger. Thomson's Vine manure mixed with clear water will be found a good stimulant to encourage the roots to the surface. Judgment must be used as regards top-dressing, but only add about an inch of soil at a time. Pinch out all laterals as they appear, and cut away portions of the foliage to let the fruit have the full benefit of the sun. Tomatoes are very subject to attacks from white fly, which can be eradicated with the XL All Vaporiser.—P. R.

THE FIG.

FEW of our choice dessert fruits are more eagerly sought after for home use than well-grown Figs, while for exhibition purposes they are also held in high esteem. It will be my aim to give a few notes from experience on the cultivation of this luscious fruit. Frequently a structure is set apart solely for their cultivation, and it should be light, with adequate means for ventilation and efficiently heated, so that in case of hard forcing the undue heating of the hot-water pipes would not be necessary. The border should be restricted, not too deep, but thoroughly drained. We get more fruitful trees when the roots are somewhat confined, and the Fig is very impatient of stagnancy, although, during the season of growth, abundant supplies of water will be required; indeed even in the resting season the border should not get so thoroughly dry as to be

injurious to the well-being of the tree, or the young fruit will drop badly. Cleanliness in all things must be rigidly observed.

Assuming the trees have naturally cast their leaves, pruning should be taken in hand, and experience is necessary in this operation, as thoughtlessness would soon ruin the fruiting properties of the tree. No more old wood ought to be taken out than will permit that left behind being laid in at an even distance of, say, 5 or 6 inches, more or less, according to the condition of the tree. After pruning, thoroughly wash all glass and woodwork, and, if necessary, dress the trees with Gishurst compound, a sharp look out being kept for scale, which, if left, soon multiply, and give the leaves in the summer an unsightly appearance, besides being injurious to the fruit. In training the trees, endeavour to get every branch and growth straight and evenly distributed. Look to the border after all training has been completed, taking off the surface soil down to the roots, and, if at all dry, afford a good watering of clear water, afterwards adding a rich root-enticing compost as a top-dressing. The Figs are then ready for starting, and, until such time as this comes, should be kept quite cool, merely excluding frost.

In many places early forcing of Figs is practised by the means of young trees in pots, these, if necessary, having been repotted on the fall of the leaf, not giving too great a shift. They ought to be started early in December if ripe fruits are required by the middle of the following April. Plunge the pots to the rim in sweet fermenting material, having a temperature of about 75°. The house should be started with a temperature of 45° to 50° by night, allowing 5° more during the daytime. Gradually raise the temperature as growth advances, judiciously watering with both clear water and liquid manure, the latter more especially as the fruit is swelling. Frequent syringings to keep insects at bay, thoughtful stopping at four or five leaves, thinning of weakly growths, and gradually hardening as ripening approaches, constitute the chief items in this direction. Care will be needed when the fruit has reached that stage when it appears stationary, as no hurrying must then take place, or disaster may ensue.—SEMPER.

(To be continued.)

FRUIT FORCING.

Cucumbers.—*Raising Plants in Frames.*—The material for making the seedling beds being in a fit condition for turning over and mixing with leaves, so as to induce a sweet regular heat, a site for the bed should be chosen with a full southern aspect, and having shelter to the north, as that of a wall. If the ground be rather higher where the bed is to be formed than the surrounding level, all the better. Mix, and beat the materials well down with the fork as the work proceeds, making the bed about 5 feet high at the back and 4 feet 6 inches in front, which will allow for settling, as it will do about one-third. A few Pea sticks placed across and along the bed at intervals not only prevents overheating, but admits of the heat from linings being conveyed to the interior of the bed. For early work frames with an inner lining are an advantage. They are formed by placing quarter-inch boards 11 inches in depth at the back and 9 inches in front, with the bottom edges level with the bottom of the box, nailing strips of wood an inch wide and thick on the inside of the frame, and then the boards, which form a cavity all around the inside of the box, and thus top heat is furnished. In a week, after making up the bed and putting on the frame and light, level the surface of the bed, replace the box, and place in sufficient sweetened fermenting material to raise the inside to within 4 inches of the inner casing, placing partially decayed, rather dry leaves, or sifted spent tan on the manure, and bringing up level with the casing, which will allow of the pots being plunged about 3 inches.

To raise the plants, 3-inch pots are half filled with light rich loam, placing one seed in the centre of each pot, covering about half an inch with fine moist soil, so that no water is needed until after germination. Space is thus left in the pot for top-dressing, which is preferable to moving the plants. A square of glass placed over each pot will hasten the germination, but it must be removed as soon as the plants appear. The plants from a sowing made early in February will be ready for planting early in March, and will afford fruit at the end of April or early in May.

Vines.—*Early Forced in Pots.*—Although it is desirable to thin the berries somewhat freely, it is essential that enough be left to form compact bunches. Maintain the temperature at 65° at night, falling to 60° on cold mornings, 65° to 70° by day, admitting a little air at 75°, increasing the temperature with sun heat to 80° or 85°, closing the house at 80° with a prospect of an advance to 85° or 90°, at the same time damping the house. Sprinkle the paths and walls in the morning and evening when sharp firing is had recourse to, but avoid causing a steam. Great care is necessary in ventilating, admitting a little air at a time so as not to reduce the temperature, but to prevent its rising suddenly to an unsafe point. Afford copious supplies of liquid manure a few degrees warmer than the mean temperature of the house.

Early Forced Planted-out Vines.—Remove all duplicate bunches, thinning the berries immediately they are well formed. Give attention to stopping bud laterals and tying bud shoots. It is assumed that the bearing growths have been stopped two or three joints beyond the fruit. Where the space is restricted they may be pinched to one joint above the bunch. In any case the axillary growths can be stopped at the first joint, and to one leaf afterwards as fresh growth is made. If this is likely to interfere with the principal leaves the laterals must be rubbed off except from the two lowest leaves, those on a level with and above the fruit being stopped to one joint. The principal foliage should be fully exposed to light and air, overcrowding being highly prejudicial. Very close stopping, however, is not to be recommended where there is room for extension, as the increase of foliage promotes root action, therefore preserve all foliage consistent with its full exposure to light. If there are no fermenting materials or evaporation troughs in the house the floors and borders may be sprinkled with diluted stable drainings. Where the soil is of a very porous nature, or the borders of limited area, the whole of the surface of inside borders may be covered with sweetened horse droppings, then the water applied passing through the light mulching will excite root action, and with the leaves in good condition the berries swell freely.

Houses in which the Vines are in bloom should be maintained steadily at 65° at night, 70° to 75° by day, and 5° to 10° more from sun heat, with 5° more all round for Muscats. Black Muscat (Hamburgh) and even Madresfield Court, also Muscat of Alexandria and other varieties liable to set indifferently, may be assisted by tapping the bunches every day, or more certainly by applying ripe pollen, drawing a brush lightly over the bunches. A constant circulation of dry warm air is conducive to a good set, and it is advisable not to stop the growth closely during the setting period. If any varieties are deficient of pollen it may be taken from those affording it freely, such as Black Hamburgh, collecting it on a sheet of paper, and then loading a brush with it, pass it over the bunches of the shy setter.

Vines Started at the New Year.—Continue to syringe the rods twice a day until the bunches are formed, when it is best discontinued, but maintaining plenty of atmospheric moisture by damping the paths and borders two or three times a day. Increase the temperature to 55° at night, and from that gradually to 60° after the buds start, 60° to 65° by day, with an advance from sun heat to 75° and ventilation in accordance with the state of the external air. It is desirable to keep up a supply of ammonia in all houses by turning over any fermenting material, sprinkling sweetened horse droppings on the border, damping with liquid manure or having the evaporation troughs kept filled with the same.

Houses to Afford Ripe Grapes in July.—Start the Vines at the beginning of February. There is no need to cover the outside border with more protective material, such as leaves or litter; these suffice to prevent the soil being frozen. If the Vines are planted outside, see that the stems are well protected by haybands, for if these become frozen after the Vines have started into growth, it is certain they will receive a severe check and the crop be lost. Syringe the rods two or three times a day, maintaining a temperature of 50° at night and 65° by day with sun heat. Supply inside borders with water or liquid manure, but only to bring the soil into a moist condition, taking care not to make it sodden and sour.

THE KITCHEN GARDEN.

Early Celery.—If Celery is wanted very early seeds should be sown at once, giving the preference to a good white variety. The seeds should be sown on the surface of pans of fine soil made level and moistened. Cover very lightly, if at all, with fine soil, place on a mild hotbed or in a moist, brisk heat, cover with a square of glass, shade heavily, and be careful not to disturb the seed by careless watering. When large enough prick them in boxes of light loamy soil, and still keep them in a light position and gentle heat. Subsequently they may be grown in frames or in 6-inch pots.

Onions.—If extra fine Onions are required for competition at shows, the plants to produce them should be raised under glass and duly planted out. This plan is also the best to follow by all who have hitherto experienced any difficulty in obtaining heavy crops of sound, good keeping bulbs. When raised in gentle heat not a seed or a plant is wasted, an early start is insured, and a perfect maturation of bulbs inevitable. If the seed is sown somewhat thinly in boxes of light loamy soil the plants may eventually be moved from the boxes to where they are to be grown to their full size, but if raised thickly they ought to be pricked into other boxes and kept in these for a time. Press the seed into the soil, cover with a little fine soil, and place in a moderately warm house, pit, or frame to germinate.

Early Leeks.—For ordinary purposes the plants may well be raised in the open ground, sowing the seed late in February or early in March, but if fine Leeks are wanted comparatively early sow the seed and treat the plants throughout similarly to Celery.

Carrots and Radishes.—For these a gentle, lasting heat is required, and the hotbeds may be formed either in pits or in a sheltered open position somewhat larger than the frames to be stood on them. About 6 inches of light sandy soil, such as may be obtained by sifting over a heap of old potting soil, is enough for the surface. Sow the seed, directly all danger from overheating of the hotbed is past, in shallow drills. If Carrots and Radishes are grown together, as they may well be, the former should be sown in drills 8 inches apart, and midway between these a row of Radishes. In any case, thin sowing to obviate the necessity for thinning, should be practised, covering the seed with a little fine soil. The Radishes will be ready for use and drawn long before the whole of the space is required by the Carrots.

Early Potatoes.—Where the planting tubers were stored in heaps the mild winter has caused them to sprout early, and the shoots are too long to save. Weather permitting, all should be cleared of their long shoots and be spread out thinly in shallow boxes, and placed in a cool, light position to start afresh. By planting time all ought to be furnished with two or three short thick sprouts, and as far as the round and pebble shaped varieties are concerned, will not have been greatly weakened. It is the Ash-leaf varieties that suffer the most from the loss of the primary sprouts. These ought to be kept thinly stored, and in a light position from the first. Any tubers that are to be forced in pots, pits, or frames, ought first to be started in boxes, arranged sprout end uppermost, a moist atmosphere and gentle heat causing a healthy, strong growth. In the meantime prepare mild hotbeds and soil, and by the time the latter is well warmed through and the strong heat declined somewhat, the sprouts will have commenced forming roots and be in excellent condition for planting.

THE BEE-KEEPER.

WORK IN THE APIARY.

DURING the long winter evenings much work may be done in the apiary which will be beneficial to the bees when the busy time comes. More often than otherwise we fear very little preparation is made by bee-keepers beforehand, or there would not be so many complaints from them during the busy season of their inability to procure from dealers in bee appliances the goods they require. It is unreasonable for them to expect their orders to be satisfactorily carried out when a short notice is given. If a little forethought were given to this matter it would be to the advantage of both buyer and seller.

Early in the new year it is our practice to carefully examine all the utensils we use in connection with bee-keeping and make a note of our requirements, and whilst the various articles are passed through our hands they are cleaned if necessary, and placed where they may be easily found when required for future use. In well managed apiaries a correct list will be kept of all sections and bottles on hand. It is useless waiting until they are required, and then expect the dealer to supply them at a moment's notice. The honey season is usually so short in this country that a delay of a few days in obtaining the necessary articles may make all the difference between the success or failure of the honey crop.

Another advantage bee-keepers derive by obtaining their goods at this season is—the majority of dealers will allow a liberal discount on all goods supplied before spring. We, therefore, cannot too strongly impress on bee-keepers the great benefit it will be to them to make their arrangements beforehand. Combs, whether in frames or sections, should at the same time be removed from the boxes or wherever they are stored, and examined to see if the wax moth has molested them, as if left undisturbed the combs would soon be ruined. If previous instructions have been carried out, and carbolic acid is again sprinkled on the wrappers in which they were enclosed, little damage will be done. They may then be placed in the same position they previously occupied.

SPARE HIVES AND FRAMES.

It does not require a tradesman to make either frames or hives, and anyone who felt inclined to try their hand at this interesting work might do so most successfully during the winter evenings. We would advise those who have not previously attempted, to procure a hive that has been properly made, and there need then be no difficulty in making another equally good out of a box that can be obtained from grocers and others for a few coppers.

Whether bee-keepers obtain their goods ready made or they manufacture their own, it is advisable to have them all of the same dimensions, as they are so much easier to manipulate, and if extracted honey is the chief aim of the bee-keeper, it is sometimes a decided advantage to be able to practise the doubling system, and it is a very simple operation when all the hives are of the same dimensions and each one has a loose floor board.

Frames ready made may now be obtained at such a low price that many bee-keepers prefer to buy them. There is one strong point in favour of the frames turned out by our large manufacturers is they are made true to measurement, and hang square in the hive. They are, however, often lightly made, and on several occasions we have seen the top bar break whilst lifting a fully sealed comb out of the hive. We therefore prefer the home-made frames if ordinary care is taken in making them. A block is necessary for this purpose; it is then impossible to make one larger than another; a little practice, however, is required to make them so that they hang perfectly square in the hive, otherwise some frames will touch each other, and others may be a couple of inches apart.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Fruit and Flower Farming (H. W.).—We have no justification for publishing the addresses you suggest, and thus causing busy people to be inundated with letters, even though the recipients did not, as certainly many of them would not, reply to the applications. If you cannot obtain what you require otherwise, you might try the effect of advertising in the usual business way in which persons make known their "wants."

Begonia Gloire de Lorraine (W. C. S.).—This is one of the very best plants now grown for winter flowering. After blooming the plants should be kept a little cooler than before and rather dry at the roots for three or four weeks. Then place them in heat and repot as soon as they begin to grow freely, using a compost of two parts loam, one part of peat or leaf soil, with sharp sand added. Pot very firmly. As soon as good young cuttings are formed they should be inserted in sandy soil and kept close in a hand-light placed in a warm house. Pot as required, and grow in a temperature of 60° during the spring months. Throughout the summer the plants succeed well in a cool house or frame. Stopping the young growths should be practised three or four times during the summer. The plants will then form dense bushy little specimens. During the flowering period provide a temperature ranging between 55° and 65°.

Soil for Rhododendrons (Rhodo).—The best mixture, next to peat, for these shrubs is the turfy surface of a pasture where the soil is of a sandy or gravelly nature, cut about 2 inches thick, chopping and adding one-fourth of well-decayed cow manure. In preparing the beds the subsoil should be sufficiently porous or drained to prevent water becoming stagnant beneath and around the plants. As your soil has a clay subsoil it will not do to make beds a depth of 3 feet without having drains from them, and somewhat lower, with proper fall and outlet, or you would only have pits for holding water. Besides, a depth of 2 feet, or at most 2½ feet, is quite deep enough for Rhododendrons, and we should only have the latter in your case, with 6 inches of rubble (preferably freestone, certainly not calcareous material) placed in, not forgetting the drains to carry off superfluous water, and on the rubble place a layer of turves grass side downwards. This will give the plants a chance. They do not object to a clay subsoil if it be well drained. If peat is procurable it should form the bulk; leaf soil and sandy loam may be added more freely when they can be readily obtained, and dried cow manure is an excellent addition. Here is a good mixture:—Peat two parts, leaf soil and sandy loam one part each, dried cow manure one part. The object in this mixture is to save the peat, mixing all well together. Another good mixture is:—Half-decayed leaves three parts; turfy surface of a pasture, cut about 3 inches thick, one part; rough white or other sharp sand half a part; chop but not beat the soil, and use it as rough as possible. If the plants have 6 inches depth of this below the balls, and it is brought up around them and over so as to cover them about an inch, they will thrive, giving a top-dressing every two years of cow manure. Yet another recipe may be given:—Half-decayed stable manure, from horses bedded with sawdust, one part; turfy loam, of a sandy or gravelly nature, two parts—the loam chopped up and mixed well with the sawdust material. The best Rhododendrons we have grown were planted in light turfy loam over good drainage, the beds being kept well mulched with the half-decayed sawdust and manure, loose box material, about a sixth of sharp sand being added to it and intermixed. Now choose for yourself, it being a question of making worthy use of available material.

Calanthes (Foreman).—The spikes are most creditable, and it is plainly apparent that your methods of cultivation are excellent. The names you give are correct. The Poinsettias are very fine.

The Vegetable Pear (N. B.).—By this we presume you refer to Vegetable Marrow. If so, the seed should not be sown until the end of April or early in May under a wall for shelter, and they should be placed about 6 feet apart, it being usual to sow three seeds in a place to make sure of a sturdy plant, leaving the strongest one when they are showing the second rough leaf. The plants do not transplant well, it being usual to raise them in pots so as to overcome the difficulty and get them forward for planting out.

Pruning a Shrub (H. F.).—The shrub, apparently *Pyrus Maulei*, should be pruned in the summer—that is, have the growth regulated and laid in so as to cover the space evenly, any foreright growths being shortened to a few leaves. When this has been neglected the pruning should be attended to now, cutting away any excessive growths so as to keep near the wall, as it flowers on the well-ripened wood. It is usual to go over the shrub about July, regulating the growths by cutting back the shoots not required for filling space, and again in the autumn or spring, in order to keep it within bounds.

Vallota purpurea—Narcissi Bulbs (Idem).—This plant usually flowers in the late summer or early autumn, but not in the spring. The plants should be kept supplied with water after flowering, and grown in plenty of light in a cool house kept safe from frost. As the plants are looking healthy they will probably flower in the summer. Towards the end of May or early in June the plants may be placed outside, assigning them a sunny position, and duly supplying with water. If necessary they can be potted now, but it is advisable not to disturb the plants much, and to keep somewhat under rather than over-potted. They are perhaps best potted and planted in June and July, when they commence root action, before the flower stems are sent up; but we have potted them with success just after flowering. They should not be dried off, but have the soil moist at all times of year. 2, Narcissus bulbs will flower a second season, but not so well as the first, as they suffer more or less from the forcing process. They should be kept in a light situation safe from frost, so as to complete and mature the growths, then, when they die down, they may be kept drier at the roots or dried off, though they are best left in the pots, and these stood on a moist base. They should be potted in August or September, giving them fresh soil to grow in.

Oil Stove—Hot-water Apparatus (R. D.).—The "smell" of an oil stove is more or less injurious to vegetation, and even the "new blue-flame stoves" must do some harm, as they give off the heat at a high temperature. We have no experience of the "twelve-hours stove," but if one heating water and not giving out any fumes, it may be a suitable apparatus. We consider "the Loughborough boiler," advertised in our columns excellent for heating a small greenhouse, and it will burn either coal or coke. Being fixed outside no fumes can enter the house and cause harm to the plants.

Boarded Fences for Peaches (Scot, N.B.).—We have no experience so far north as Dundee of Peach trees on boarded fences, and hardly think them likely to succeed. Boarded fences only afford shelter from certain points, and concentrate the sun's warmth when present, not absorbing much heat and giving it out again as in the case of a wall. You must exercise judgment in the matter, as we find Peaches do not succeed against wooden fences with a south aspect in the north of England at over 100 feet above sea level. There are, of course, very sheltered and sunny situations—veritable sun traps—where "very fair Peaches have grown" under the conditions you propose, but they must be exceptional in location. 1, We consider single oblique cordon trees would be the most suitable, and the border for them need not exceed one-half the height of the wall in width, nor should it be less than one-third. 2, For dwarf trained trees, which we do not advise for your purpose, the border should be about two-thirds in width that of the height of the fence, and the trees placed twice as far apart when the height does not exceed 7 feet 6 inches. 3, The lowest satisfactory height for the fences is 6 feet, the usual height of boundary boardings. 4, The best plan of nailing on the boards is the upright. When placed horizontally the wet lodges in the joints between the boards, and they decay accordingly. Why not place the boards upright to within a foot or board-width of the ground and there place a stout board horizontally?

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (W. C. S.).—*Begonia Gloire de Lorraine*, see page 74. (W. S. J.).—1, *Cypripedium insigne*, good variety; 2, *Lælia anceps*; 3, *Adiantum cuneatum grandiceps*; 4, *Selaginella cæsia*. (O. S. P.).—1, *Cupressus funebris*; 2, *Thuja Lobbi*; 3, *Taxodium distichum*; 4, *Cedrus deodara*; 5, *Retinospora plumosa aurea*.

A FULL MILK PAIL.

It is no figure of speech to say we are greatly under obligations to our readers for the questions they at times ask us, as they serve to show the subjects most appreciated, and most calculated to be of use.

We have said it before, and we say it again, if people would only mention little difficulties, we are always willing (where possible) to help in their solution. We prefer, if our applicant can wait, to make his difficulty the subject of a paper, as we can then discuss the subject at greater length, and possibly make our answer more comprehensive.

Among all gentlemen and ladies of property living in the country, or suburbs of our towns, the first thing that occurs to them after the establishment of a garden, is the building of a cowhouse and the maintenance of a cow. They seem to consider there is a great charm

in home-produced milk, and they like to have some live stock in which they can take a real interest. Should there be a small run of grass, there is no prettier object than a Jersey or Alderney at feed during the summer months, and a little calf adds much to the interest.

But these pretty pets are not supposed to be idle, and much questioning and doubt often arises in the breast of the owner as to whether or no there should not be a fuller milkpail. The best of the Channel Islanders have not immense bags, and unless great care is taken in the feeding and management that small quantity may be made considerably less. It is not the food altogether, though that is sometimes blamed; there are other causes at work, and it only takes a small thing to put a cow out of milking gear. Cow-keeping (to have a perennial supply of milk) necessitates at least two cows, and matters must be so arranged that they do not both calve at once. A cow is not an ever-flowing fountain of milk. She must have her periods of rest, although it is quite wonderful how long she will continue, with judicious food, to give milk.

Then, again, should the breed be Channel Islanders one cow will hardly suffice for an ordinary family supply. Of course the milk is rich and good; but pints cannot be turned into quarts even by conjurers. A cow too young or too old may easily be palmed off on the unwary buyer; it is always well to employ an expert to do the buying. As to the calves—well, there is usually no milk left for them, and unless they are heifers their only end is the butcher, who may give 5s., but probably will bid 2s. 6d. for the dappled darlings.

A cowman, like a poet, is born, not made, and looking after cows, to make them do any good, is not so easy a job as it appears to the casual observer. Many and many a cow is lost from milk fever simply because the feeding beforehand has been too forcing; and many a cow has been utterly ruined by bad milking. We do not like men milkers ourselves; they are apt to be too quick and careless. It is absolutely necessary that a cow at each milking time should be most carefully striped or stropped—that is every drop of milk must be extracted; no half measures here. The richest milk is always the last, hence thorough milking cuts two ways; the cow is properly relieved, and the owner gets his full share of cream.

As the use of roots in feeding is much restricted if not altogether forbidden, the bulk of the food is of a very dry nature—that is unless it is treated to steaming or mashing. Hay, cake, and meal contain little or no natural moisture, and therefore it must be seen that moisture in large quantities be provided.

An ample supply of sweet pure water should be within reach of every cow; possibly this cannot be quite managed without much alteration in the present buildings. In that case it must be the first of the cowman's duties to see the cows have the water carried to them at least four times a day, and this water must not be served "*au naturel*," but brought up to blood heat. It is the poor man's cow which generally does the best, for the wife sees that it has properly heated drinks of various kinds.

We all know how much better we feel after a warm meal, and a cow always responds to good comfortable treatment. Some cows are turned out for a few hours daily in the winter months if not too severe. This is a plan we do not recommend unless there be a covered yard where they may exercise free from draughts. Exercise certainly does them good, but a chill is a sad impediment to a good milk flow. We believe if roots were given directly after milking, with all green parts cut off, the milk would not suffer in taste, and the cow would be benefited by a change in diet. There might be a difficulty sometimes about getting a few Mangolds, yet there are usually plenty of small farms where a load or two can be procured.

A cow tied up during a long cold winter requires change of diet to keep her milk supply even and regular. All sorts of meal, almost, may be used to make warm broths or gruels, and a pailful before the afternoon's milking has a very desirable effect. These meals must be regulated by the market price, sometimes one sort, sometimes another, being cheap and abundant. A few Carrots, too, make a pleasing variety, and are nowadays easily procurable.

For the use of amateurs we copy out some dietary tables found in a book on Jersey management by Vinton & Co.:—

EXAMPLE I.			
Carrots	12 lbs.		
Chaff, Oat straw	5 lbs.		
Chaff, good hay	5 lbs.		
Decorticated cotton cake	2 lbs.		
Crushed Oats	2 lbs.		
Good hay	7 lbs.		

EXAMPLE II.			
Inner leaf Drumhead Cab-			
bage	18 lbs.		
Chaff like No. 1	10 lbs.		
Linseed cake	2 lbs.		
Crushed Oats	2 lbs.		
Bran... ..	2 lbs.		
Good meadow hay	7 lbs.		

EXAMPLE III.			
Mangolds	14 lbs.		
Chaff as above	10 lbs.		
Decorticated cotton cake	3 lbs.		
Maize meal	3 lbs.		
Good hay	7 lbs.		

EXAMPLE IV.			
Mangolds	14 lbs.		
Chaff	10 lbs.		
Decorticated cotton cake	2 lbs.		
Maize meal	2 lbs.		
Malt, sprouted	2 lbs.		
Good hay	7 lbs.		

These four examples at any rate give variety, and are very fairly balanced—i.e., no class of food unduly predominates above another. There are tissues to build up, the life of the unborn calf to provide for, and an ever-gaping milkpail to be filled twice a day with milk rich in fat.

WORK ON THE HOME FARM.

Ploughing is all done, and as we do not believe in cross-cutting until February we must perforce turn our attention to the yards, which are now so full of muck that it is difficult to keep the cattle out of the cribs. So we must, or rather the horses must, try and struggle with heavy loads over heavy roads and heavier land to convey the muck to the hill, or for spreading direct.

Where land is clean enough, were it not that the heavy carting over it and consequent treading would make it very solid and the horse labour would be so severe, it might be worth while to consider whether muck for Turnips would not be better spread on the land now. Cross-cutting might soon follow, burying or partially burying the manure; and although there might be a slight loss of free ammonia, we fancy that the potash and phosphate in the manure having time to become more soluble (shall we say available) would more than balance any such loss. This much is certain, that on soils where a Turnip plant is a difficult object to attain, manure, if used at all, should be ploughed in during the winter if possible.

Turnips, with the help of the mild weather, are holding out better than was expected, but are now showing strong signs of running to seed. Swedes in such a case might yet be taken up and stored with advantage, for with every inch of new growth the feeding value of the roots will be enormously reduced, whilst if a severe spell were yet in store for us the loss would be quite as great from frost as from running to seed.

The season is very favourable for making further sowings of Wheat. Will farmers, however, consider 27s. per quarter sufficiently encouraging to make further sowings? We think not, and except on very dry soil should advise the growth of Barley or Oats as being more likely to be profitable.

REMARKS.

- 15th.—Fine early; incessant rain from 9.30 A.M. to 2 P.M.; dull and damp after.
 16th.—Mild day, overcast early; showery from 9.30 to 10.30 A.M., at 1 P.M., 4.10 P.M., and 5.20 P.M.; bright sun from 10.50 A.M. to noon and 1.25 P.M. to 4 P.M.; bright night.
 17th.—Bright and fresh from early morning to sunset; rain from 7.30 P.M.
 18th.—Rain till 3 A.M., mild and humid after; fair day, and spots of rain at night.
 19th.—Overcast, with spots of rain or drizzle at intervals, and slight showers in afternoon.
 20th.—Fair early; faint sun at times in morning; almost continuous rain or drizzle from noon; S.W. gale at night.
 21st.—S.W. gale with rain or drizzle early, and in evening; overcast day, but gleams of sun about noon.
 Mild; wet to stormy.—G. J. SYMONS.

BARR'S SEED GUIDE FOR 1899 IS NOW READY,

And will be Forwarded Free on Application.

BARR'S SEED GUIDE contains a Select List of the best Vegetable Seeds and most beautiful Flower Seeds. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. SENT FREE ON APPLICATION.

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS contains a liberal assortment of the following useful vegetables: Beans (Broad and French Beans), Beet, Borecole, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrot, Cauliflower, Celery, Colewort, Corn Salad, Cucumber, Cress, Endive, Herbs, Leek, Lettuce, Melon, Mustard, Onions, Parsley, Parsnips, Peas, Radish, Salsify, Savoy Cabbage, Scorzoneria, Spinach, Tomato, Turnip, and Vegetable Marrow.

Other Collections of Barr's Vegetable Seeds, 5/6, 7/6, 12/6, 42/-, 63/- and 105/-. These Collections sent carriage paid on receipt of remittance. Full particulars on application.

BARR'S CHOICE FLOWER SEEDS.—Our Catalogue contains a Select List of all the most beautiful Annuals and Perennials. Special Collections for all purposes, and many Sterling Novelties.

All Seeds sent Carriage Paid on receipt of remittance.

BARR & SONS,
12 & 13 King Street, Covent Garden, London.
Nursery: LONG DITTON, SURREY
(Surbiton Station, S.W. Railway).

ANT. ROOZEN & SON'S GUINEA COLLECTION OF VEGETABLE SEEDS

CONTAINS—

- | | |
|---|---------------------------|
| 16 Pints Peas (including Al, Marrowfat, and Late Queen) | 2 Pkts. Endive |
| 6 Pints Broad Beans | 1 " Gourds |
| 2 Pints Dwarf French Beans | 1 " Kohl Rabi |
| 1 Pint Scarlet Runner | 1 " Leek |
| 1 Packet Asparagus | 3 " Cabbage Lettuce |
| 2 Pkts. Beet | 2 " Cos Lettuce |
| 2 " Borecole | 2 " Melon |
| 3 " Broccoli | 6 ozs. Mustard |
| 2 " Brussels Sprouts | 4 " Onion |
| 3 " Cabbage | 2 Pkts. Parsley |
| 1 " Capsicum | 2 ozs. Parsnip |
| 4 ozs. Carrot | 4 " Radish |
| 2 Pkts. Cauliflower | 1 Packet Salsify |
| 2 " Celery | 2 Pkts. Savoy Cabbage |
| 1 " Couve Tronchuda | 2 " Scorzoneria |
| 4 ozs. Cress | 6 ozs. Spinach |
| 3 Pkts. Cucumber | 6 Pkts. Herbs |
| 2 " Egg Plant | 2 " Tomato |
| | 4 ozs. Turnip |
| | 1 Packet Vegetable Marrow |

For other Collections from 10/- to 100/- see our Seed List.

Orders for VEGETABLE SEEDS of 20/- and upwards sent Carriage Paid.

Orders for FLOWER SEEDS of 3/- and upwards free by Post.

LIST will be sent post free on application to their Offices at OVERVEEN, nr. HAARLEM, HOLLAND, or to their General Agents,

Messrs. MERTENS & CO.,
3, CROSS LANE, LONDON, E.C.

No. 971.—VOL. XXXVIII., THIRD SERIES.

NOVELTIES RAISED AT WINDSOR AND OSBORNE.

It is Messrs. CARTERS' privilege to offer the following new and choice productions to the notice of gardeners and private cultivators.

BRITISH QUEEN MELON.

Raised and named by Mr. OWEN THOMAS, Supt. of the Royal Gardens, Windsor. Awarded the First-Class Certificate R.H.S. Pronounced by the Committee to be not only the very best white-flesh melon ever submitted, but the richest flavoured of any colour. Awarded the Gold Medal of the Royal Caledonian Society in association with other fruit exhibited by H.M. The Queen.

In sealed packets, price 2/6 and 3/6 each, post free.

ROYAL OSBORNE CUCUMBER.

A valuable cross between the Rochford and an improved type of Telegraph, raised and named by Mr. GEORGE NOBBS, Head Gardener to H.M. the Queen at Osborne. In our opinion it is one of the best all the year round varieties introduced in recent years.

In sealed packets, price 2/6 & 3/6 each, post free.

ILLUSTRATED CATALOGUES, POST FREE.

WE HOLD THE ENTIRE STOCK OF SEEDS
OF THESE TWO NOVELTIES.

CARTERS,

The Queen's Seedsmen.

Only Address—

237, 238 & 97, HIGH HOLBORN, LONDON.

The 32nd Edition is Now Ready.

200 PAGES.

150 ILLUSTRATIONS.

PRICE SIXPENCE, POST FREE.

(By Parcel Post—it is so large).

EVERY AMATEUR SHOULD POSSESS A COPY.

AN ABRIDGED EDITION OF OUR CATALOGUE CAN BE
HAD FREE ON APPLICATION.

CHRYSANTHEMUMS.

Our Stock is perfectly clean. We never had Rust or Disease in our Collection. Cuttings from 1/10 per dozen.

SWEET PEAS.

All Standard Named varieties are offered per 1/2-oz. Packet. From 3d. per Packet.

SEED POTATOES.

These are quoted in small lots, and Carriage Free to destination.

DOBBIE & Co.,
SEED GROWERS AND FLORISTS TO THE QUEEN,
ROTHESAY.

Journal of Horticulture.

THURSDAY, FEBRUARY 2, 1899.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

RAISING AND GROWING MELONS.

PROBABLY no fruit is more generally mismanaged than Melons. Of course I am fully aware that there are exceptions, and that many handsome crops are produced by growers who thoroughly understand the details of culture requisite to attain success. Those persons who attend summer exhibitions are well aware of the number of inferior Melons met with as far as flavour is concerned. From a dozen fruit of both green and scarlet seldom can more than three of really fine flavour be found. When this happens during the months of July, August, and September, it is safe to suggest that the cultural conditions under which all were produced could not have been of the best.

The awarding of prizes to Melons solely by their appearance, with perhaps the sense of smell thrown in, has been advocated, but it, in my opinion, would be a grave error. Melons with a rough skin are frequently the most luscious, and *vice versa*. As a rule scarlet flesh varieties are inferior in flavour to those with green flesh, and very seldom are white flesh Melons first prize winners. Scarlet Gem held its own as the finest flavoured Melon in that section for at least twenty years, and never was there a more rugged, rough looking fruit. This variety has perhaps taken more prizes than any other, not even excepting Hero of Lockinge, which has been a standard variety in the green flesh section for a number of years.

In justice to many gardeners, however, it must be said that the convenience for Melon culture is not nearly so good in some gardens as it should be, and growers who are handicapped by ill-adapted structures have some excuse if inferior samples are produced. A properly heated low-roofed house is undoubtedly the best, and span-roofed structures, about 10 feet to 12 feet wide, are perhaps better than an ordinary lean-to house, because more space is provided for a greater variety, and two crops can be accommodated at the same time, while light and air are at command in greater amounts if required.

Where only one house can be used for Melons

No. 2627.—VOL. C., OLD SERIES.

it is wise to grow several varieties, as the season of ripe fruit is thus prolonged, even under the same treatment. Obviously, when these conditions prevail, greater care is necessary in fertilising the flowers if seeds are to be saved. In a case where seed sowing is the primary consideration, one variety in a house is the correct method to pursue.

Heated pits are often requisitioned for Melons, and even in frames, with no artificial heat beyond a small quantity of manure to give the plants a start, many good crops have been produced. Under such circumstances, more attention to the details of air giving and pinching the shoots is necessary, and if the weather is uncongenial—partially dry and warm—during the months of July and August, Melon growing in frames is a long way from being a pleasurable undertaking.

Plants growing in frames admit of little variety in the form of growth, as all must be, what might not inaptly be termed, bushes. In a house various methods of training are adopted, but the cordon system is the best. Plants 15 inches apart give a crop more quickly throughout the house, because if one plant does not give the requisite number, there is no appreciable difference in the whole. Two or three fruits are soon "set," which swell rapidly, and thus afford time for a successional crop, either from the same or later raised plants. Many cultivators aim to have two crops from the same plants. Another method is to have the plants 4 feet apart, and train the shoots to the right and left, but much time is then required to furnish the roof, and a longer period is occupied in obtaining the necessary number of fruit.

The present is a suitable time to sow seeds to have ripe fruit in May, and only too often is failure clearly traceable to a bad stock at the outset. The plants in separate pots must be sturdy, and have the first leaf close to the seed leaves, and not, as is frequently the case, attenuated, for such plants never thrive satisfactorily. They are the result of thick sowing and lack of after attention in various ways. Let the seeds be sown singly in 2½-inch pots, containing fresh loam, and covering with half an inch of moist soil. Gentle bottom heat favours rapid vegetation, and immediately the seedlings are through the soil place the pots on a shelf close to the glass in a temperature of not less than 65°. In such a position they grow sturdily, and must be transferred to larger pots when a good number of roots have formed.

Some growers employ loam only for planting, considering the use of manure in any form to be harmful, and this, in my opinion, is one of the chief causes of failure. For years I upheld the same view, but a change of procedure, in which manure was an important agent, brought results far more satisfactory than anything I attained to before. It is obviously impossible for plants growing slowly in poor soil to give as luscious fruits as those in a better medium will do. An improvement in the quantity and quality of the foliage must have a beneficial effect on the fruit. Half-decayed cow manure and loam, in the proportion of three parts of the latter to one of the former, make the best compost, which can scarcely be too firm at planting time for Melons. When the roots appear on the surface is the time to add an inch or so of cow manure and loam in equal parts, and the increase in size and colour of the foliage will be an early indication that the plants enjoy the food.

In planting, a rather high ridge is formed along the centre of the bed, and the collar is kept well above the soil as a preventive of canker, which then, with care in watering, ought not to trouble anyone. Low planting, so that the stem above the seed leaves is partly buried, or so placed that it is continually moist, is productive of canker, and diseased plants are difficult to cure. Powdered charcoal, lime, and sulphur, are suggested, but prevention is my watchword with this as well as other foes. Cordon-trained plants should not have the points removed until they have reached the limit of space. Pinch out the point of all side shoots one joint beyond the fruit, and avoid overcrowding the foliage; it is better to remove a fruitless shoot than hinder maturation and encourage weak growth.

Abundance of moisture both at the roots and in the atmosphere

is absolutely necessary after the fruit is set and swelling; the former to assist growth, and the latter to ward off insect pests, such as red spider, thrips, and mealy bug, all of which are prejudicial to success. Directly the first sign of ripening is visible some persons withhold water from the roots and the leaves, and the latter is correct, as when moist the fruit is more liable to crack, but the foliage ought to be maintained in active condition up to the time of ripening, and to insure this the soil at the roots must never become quite dry. Abundance of air must be admitted as the fruit ripens, and a buoyant atmosphere maintained, damp air being positively injurious.

An article of this nature should contain some reference to varieties, which are at the present time so numerous as to bewilder the inexperienced. The following I have tried and can recommend:—*Green-fleshed*: Hero of Lockinge, William Tillery, Windsor Castle, Imperial Green, Sutton's Royal Jubilee, Sutton's Perfection, and Golden Perfection. *Scarlet-fleshed*: Blenheim Orange, Invincible, Triumph, and Scarlet Gem.—E. MOLYNEUX.

THE WEATHER OF 1898.

THE weather of the past year has been of a very interesting character, and has shown to a remarkable extent the great dependence of agriculture on the meteorological conditions prevailing during a season. A good farmer may mitigate the injury caused by unfavourable weather by making the most of every chance he may have to counteract its effects on his crops, but he cannot do more. It is useless, for instance, for him to expect a full crop of hay if the spring be rainless, or a good harvest if the summer be only one in name. Horticulturists also, to a great extent, have to depend on the weather conditions for a successful season.

During the past year the early months were of an exceptionally favourable character, the weather being open and mild, with small rainfall—an unusual accompaniment of a warm winter. With the coming of spring, however, a great change occurred for the worse, the weather becoming for the time of year very cold, damp, and sunless, and towards the end of May forebodings of a disastrous season began to be heard on all sides. With the advent of June the outlook became more unpromising still, for during the first few days very inclement weather prevailed, snow and sleet showers falling in many places. In the third week, however, a steady improvement in the weather began, and for the remainder of the summer sunshine and heat became the rule, the warmth and sunshine extending well into the autumn.

This glorious weather completely changed the character of the season, although there was still occasion of complaint—especially over the south-eastern counties—in the unusual absence of rain. After some of the hottest weather experienced during September for over half a century, the inevitable change from summer to autumn took place on the 18th of that month, although the rainfall continued very deficient over the greater part of our islands until well into October. The last three months of the year were, like their immediate predecessors, much warmer than usual; but unlike them they possessed an abundant, though by no means excessive rainfall, so that while the fields yielded an abundant supply of grass farmers had plenty of opportunity to prepare the soil for the crops of the coming year. Upon the whole, therefore, the past season must be reckoned to have been for agriculture generally one of the most favourable of recent years, and it well exemplifies the truth of the well-known saying that "A dry year never beggars the master."

In a short article of this kind it is impossible to give an exhaustive account of the rainfall of the year; but the general distribution will be seen from the following table, which gives the details of fall at eight selected stations situated over our islands.

THE RAINFALL OF 1898 AND DEPARTURES FROM AVERAGE.

Departure from average		-3.44	-3.49	-2.29	-3.33	-4.03	-7.78	-5.38	-7.02

The rainfall was deficient, therefore, practically over the whole of our islands, the deficiency being greatest over the south and south-eastern parts of England. In the extreme north, however, there was an excess of rainfall, Sumburgh Head (Shetland Isles), for instance, reporting 5 inches of rain more than the average. Taking our islands as a whole, it will be seen that the driest months of the year were January and July, although over the south-eastern counties September was by far the most deficient in rainfall.

The mean temperature of the twelve months is considerably in excess of the average. In the second table given, the means for each month, and also for the year, at eight stations situated over our islands, will be seen.

THE TEMPERATURES OF 1898 AND DEPARTURES FROM AVERAGE.

The means are those of the daily maximum and minimum readings, and are uncorrected for diurnal range. With the exception of March, May, June and July, the means for each month are well above the average, the greatest excess being shown by the two winter months, January and December. The temperature of December especially was extraordinarily high; at Liverpool and Bristol the means for the month closely approach that of an ordinary April, while at Valencia the mean exceeded it.

Atmospheric pressure over our islands ranged from a maximum of 30.60 inches and more during the last half of January, over the southern counties of England; to a minimum of 28.30 inches and less in the north of Scotland on the 28th of December. Snowstorms, as might be expected, were not much in evidence during the year. There were only two falls of importance; the first an exceedingly heavy, but rather local storm, affecting the counties of Hants, Devon, Dorset, and Somerset, on the 21st and 22nd of February; and the second, a fall chiefly affecting the north and north-west of England, on the 22nd and 23rd of November.

Thunderstorms were chiefly prevalent during June and August. They were very severe and brilliant over the south-west of England, on the 18th and 21st of the latter month. One of the features of the year was the frequent displays of aurora; on the 9th of September especially one occurred of exceptional brilliancy, which was visible over almost the whole of our islands.

Gales were not very prevalent during the year. The severest occurred on the 24th, 25th, and 26th of March, from the north-east, generally over our islands; on the 17th and 18th of October, from the east, over our northern districts; and on the 27th of December, from the south and south-west, over the greater part of the kingdom.—H. H. HARDING, F.R.MET.SOC.

HIPPEASTRUM PROCERUM.—Although this beautiful plant is known thirty years ago, it is still very rare, and is found only in the gardens of a few bulb specialists. It is a native of Brazil, and resembles—so far as the bulb is concerned—some of the *Crinum*s rather than the garden *Hippeastrums*, being often 2 feet long, and covered with dry membranous scales. In the T Range at Kew a fine specimen is now in flower, and it is a considerable source of interest to all who see it. The bulb of this plant is 2 feet long, and from it a stout scape bearing seven flowers is produced. The flowers are 6 inches long and 6 inches across the mouth. The dominant colour is a pretty pale blue, the throat being white with numerous blue spots, and the lower portion of the outer surface of the sepals and the stalks reddish brown. The leaves, when mature, are 1½ or 2 feet long, 1½ inch wide, strap-shaped and curved. A figure of this plant is to be seen in the "Botanical Magazine," t. 5883, under the name of "*Amaryllis Rayneri*." The plant from which that figure was taken was flowered by Dr. Rayner of Uxbridge in November, 1870. According to the description, that plant must have been much weaker than the one at Kew, for the bulb was only 10 inches long, and the flowers smaller; the colour was also slightly different. A second plant at Kew may be seen planted out in the Mexican house, where it is growing well but has not yet flowered.—W. D.

THE "LIFE AND FOOD" OF PLANTS.

THE remarks of Mr. Willis in your issue of last week (page 59) have vividly recalled to my memory the "eye-opener" I experienced with regard to the food and functions of plants when, nearly sixty years since, I had "Lindley's Theory of Horticulture" added to my then very scant library. Some of the theories of that work are now considered obsolete, but the setting forth of the parts that gases play in plant life are not so.

My object just now is to call the attention of your young readers who are in the same stage of development as Lindley's book found me when it was published, and to ask them to ponder the last paragraph of Mr. Willis's article.

The fact Mr. Willis there states is that 95 per cent. of the food of plants is drawn from atmospheric sources and 5 per cent. is obtained from the soil. I have no doubt this may startle some who have hitherto not given any heed to the elements of plants and their sources of food and life. It may also be a lesson to their elders who have not thought of the subject; and to all it cannot fail to appear that the lesson bears most of all on the culture of plants and fruits under glass.

Thanks to cheap glass, trade competition, and improved structures British gardeners are now more than ever able to apply with the greatest nicety heat and atmospheric moisture to the plants and fruits of warmer climes. The days of thin glass, small panes, numerous laps and rickety sashes, also sometimes deleterious gas from old flues are long since forgotten and have never been known by but few of this generation. It cannot, however, be denied that the means for supplying the two elements named—heat and moisture—in due and proper proportions are attended with evils that have to be reckoned with if the healthiest plant life has to be secured.

The almost air-tight manner in which hothouses are now constructed, with large sheets of glass and tight-fitting laps, in itself gives a great advantage to present day cultivators over those of the earlier part of the century, in as far as the greater amount of light and the application of heat are concerned; yet as plant life is, perhaps, as sensitive to a self-corrupted atmosphere as is animal life, the almost air-tight manner in which hothouses are now constructed favours the production of an impure, and what may be called an enervating condition of the air which they enclose, and prevents a natural change of air. It is only required to read Mr. Willis's closing sentences to be impressed with the necessity of having a constant supply of fresh air, under the influence of which plants can live and flourish.

It is not necessary to enter into the practical details of how this circulation of fresh air can be admitted to glass houses, for that is a very easy matter to accomplish according to individual circumstances. The chief point is to be thoroughly impressed with the importance of it. Let me strongly advise those who are entering on a horticultural career to thoroughly study the elements and food of plants and their functions.

I am almost afraid, Mr. Editor, that it may encroach too much on your valuable space, and try the patience of some of your readers, but now I have pen in hand I would like to look back a little and refer to some of the good results of methods that are now obsolete. As you know, old men, when they get shunted into a siding, are apt to live perhaps too much in the past. What I am thinking of is that the march of horticultural progress has carried us almost entirely out of the sight of the fermenting hotbed composed of stable litter and leaves. The clank of the engineer's hammer has completely drowned the thud of the manure fork. Who regrets this? Still it becomes a question whether in the improved appliances of supplying warmth and moisture we have not left behind us some potent-for-good condition consequent on the use of hotbeds and "McPhail" heated pits.

Who that has used these does not remember and know how well many plants used to thrive by these old appliances—how many a sickly plant when placed in these pits and frames experienced almost a resurrection from the dead? The sere and yellow leaf found in them a sanatorium, and became green and full of substance under the influence of the gases evolved by the fermenting stable litter and leaves. The largest Pine Apples that I or others ever grew were produced under the influence of these old methods; witness the 16 lbs. Providences grown in the early forties at Gunnersbury Park, and the grand Smooth Cayennes at Frogmore in what were called dung pits. The finest early Black Hamburgh Grapes I ever saw ripened in April were grown with a bed of fermenting material on the inside border, and many other things might be mentioned.

These remarks are not made under the remotest idea of recommending a return to these laborious and untidy methods of supplying heat and nourishing gases. This is far too expeditious and advanced an age for that.

What I want to do is to ask our scientists, like Mr. Willis and others, if it be not within the bounds of possibility to charge our hothouse atmospheres with what was evolved from the old fermenting material with such good results. I have myself attempted something like it by evaporating the soluble portions of the fine old Peruvian

guano—now unattainable—from troughs or pans placed in hot water pipes. The finest Pines I ever grew were so treated, as some who may read these remarks know. I have had excellent results in the case of Vines, where the inside borders were sprinkled with urine and guano. But cannot our fellow labourers and teachers, the scientists, put us on a better method of feeding more through the atmosphere?—D. THOMSON.

[We wish all our young men were as alert as some of the old ones. Space will be afforded if Mr. Willis can see his way to deal with the subject suggested.]

LONDON GARDENS OVER FIFTY YEARS.

No. 3.

DOUBTLESS the influence of ancestry upon character and tastes is considerable, and often operates to advantage, as in the case of the French refugees who came to England after the revocation of the Edict of Nantes in 1685. These emigrants, many of whom were by trade weavers, are said to have established the silk industry in Britain; and something more they did, which was to develop a love for garden flowers amongst those with whom they lived and worked.

About the end of the sixteenth century, all over France, people devoted their time and money to the culture of flowers, remarkable for their size, form, or colouring, and prominent on the list of favourites were Lilies, Tulips, Anemones, and Ranunculuses. This fact must be added, however, that the Frenchman's enthusiasm for flowers came to him from Holland, which is another feather in the Dutchman's cap. But Spitalfields, where the French silk weavers clustered, soon became famous for its choice flowers, specially Auriculas and Tulips, which figured in many shows of Georgian times. Walking thereabouts fifty years since, amid its busy population, more crowded than in any other part of London, an observer noted how both the people and their plants suffered from impure air or lack of light.

Let due honour be given to the French flower lovers of Spitalfields, and to the earlier emigrants who came in the sixteenth century from the Low Countries to teach our fellow countrymen many lessons in the art of gardening. The silk weaver was wise in his day, but an artisan or mechanic who at the close of this century gives his spare time to his garden plot has advantages that were only beginning to appear at its middle. One of these is, perhaps, more to his benefit than to that of the dealer in plants—prices have fallen all round; still, it may be said that if the profit is less the business is larger. Both French and Flemings had a liking for bulbous plants, and we need only look round London gardens or parks in winter and spring to see how their influence has extended itself; for there never has been a period in British horticulture when bulbs were so largely planted as now, not even in the Tulip mania, and the varieties our catalogues show would have amazed the gardeners of the early years of Victoria's reign. They would have been delighted, too, at the spectacle of acres of Narcissi and Daffodils cultivated for the market in some of the outlying London suburbs; a satisfactory proof that all our bulbs do not come from Holland. Many gardeners of the past generation met with disappointments in consequence of their applying various manures that did harm because they were charged with ammonia, which bulbs dislike, and the best outdoor manure for them is stated to be phosphatic basic slag; this, however, needs some precautions in use.

Again, the number of garden annuals which will thrive about large towns has been considerably increased, and seeds of such plants may be bought cheaply everywhere, and if the cultural directions are followed, a nice show may be made during the summer, afterwards the seeds can be saved for another sowing. Then the bedding out method, which, with all its defects, has held its position a good while now, made a great improvement in flower beds, and the plants required for this purpose are obtainable at a much lower figure than they were sold at in 1818. Also, for several years, the working classes of London have been benefited by a free distribution of surplus bedding plants during the summer, which is carried out annually in several parks and public gardens: besides, there are private gifts of similar kind that we seldom hear of through the Press. It is also widely known now, and acted upon, that the ordinary soil of a London garden will not produce much worth looking at unless there be a judicious application of manure. Fifty years ago we did not see what is a familiar sight along suburban streets or roads in this day, people out early with spades and baskets gathering up horse droppings and other substances which may help to fertilise the unpromising London clay.

Some of the gardeners who were accustomed to take water for their grounds from the streamlets which flowed deviously into the Thames might occasionally have found this a fertilising fluid, since, when houses increased, many of them drained into these streamlets, which were finally turned into sewers, or have dried up. In connection with London's short water supply of last autumn alarming reports were propagated about the state of the Thames, which of late has, no doubt, undergone a reduction in the average flow, partly through the large demands on it by water companies, partly because

it is not fed as once it was, the springs and rivulets along its course having greatly decreased in number.

When a lad I well remember seeing the Westbourne, though polluted, still running as an open stream across Pimlico or Belgravia, and ending in the Thames near Ranelagh Gardens. Rising at Hampstead Heath, it afterwards received the waters of the Coldbourne (Kilburn) and other brooks, and did indeed at one time supply chiefly the Serpentine lake in Hyde Park, through which it reached Knightsbridge. Actually in its best days, we are told, famous for its trout, the Westbourne's usual speed was notable, causing some people to call it the "rapid Rhone." Hence, after a heavy rainfall, it had the unpleasant peculiarity of overflowing and sending torrents of water over gardens and into houses adjacent. It reached the Thames near where Chelsea Barracks stand, after finally skirting the meadows and gardens of Ranelagh.

Then the old Grosvenor canal was not interfered with until some years after 1848, and between this and the Thames much of the land was open, and upon it they raised Cabbages, Lettuces, and Potatoes for market. It was really a remnant of the ground belonging to the "Neathouses," celebrated for its rich crops as far back as the reign of Charles II. For some distance along the canal a sloping bank covered with nettles divided it from the gardens, and I remember a Pimlico entomologist years ago getting the labourers to hunt on these nettles for the caterpillars of tortoiseshell butterflies. Not one in a thousand of the travellers to or from the busy Victoria Station recalls the fact that just there was the basin of the Grosvenor canal. Some have supposed that this was the remnant of an ancient stream which crossed what is now St. James' Park, and left the Thames at Westminster, bounding what was called the Isle of Thorney. Another rivulet which has vanished from West London rose at Wormholt Scrubs, and ran into the Thames opposite Battersea Church, receiving near the end of its course the contents of sundry ditches which intersected the old market gardens between Chelsea and Fulham. Along a part of its bed are laid the lines of the West London Extension Railway.

It seems strange to us, does it not? to think of the vicinity of Westminster as a place in which choice vegetables and fruit were raised for the Court and aristocracy, yet such was the fact; but long before the reign of our present Queen the increased smokiness of London had very much interfered with outdoor culture, and so the land was by degrees given up to other uses. The Neathouse gardens were situated between the present Vauxhall Bridge Road and Chelsea; as a place of popular resort, they are often referred to in history. Artichokes, Asparagus, and Melons are named amongst their specialities; these, and also other vegetables, were grown along the "Five Fields" adjacent, now occupied by Belgravia, and which was never so dreadful a locality as the authoress of a poem published in 1851, entitled "Belgravia," represents it to have been at one time. Part of this Five Fields remained unenclosed fifty years ago, Eaton Square and Ebury Street not being completed, much of it is still garden ground, forming centres to stylish squares. We should have seen, too, that some nurseries of small extent had come into existence about this part of Pimlico, owing to the increased demand for flowers, though before long most of these had either closed or removed to the west.

One of these which was worthy of note occupied the place of the small public garden of Ebury Square, stated to have been originally the homestead of Ebury or Aybery Farm, the fields extending many acres round in the times of the Tudors. A handsome row of Limes, planted during the reign of William III., shaded the road from Ebury to Ranelagh House; these were felled early in this century. The nursery remained open till 1884, and so vanished the last of the Westminster nurseries. The Duke of Westminster opened the square as a public garden. Efforts have been made of late to get some more important and larger West-end squares made free to all during at least a part of the year, but with no success as yet. Of course there are difficulties and objections; still to many, both young and old, access to these pleasant gardens would be a boon.

In 1848 the centre garden of Eaton Square on the north side was the nursery of Mr. Tuck. Subsequently he removed to Sloane Street, where he continued many years, occupying the ground which had belonged to Salisbury of Chelsea and Brompton, author of several books on botany and gardening. Then Dennis had a nursery where St. Barnabas Schools and other buildings stand now, near Old Chelsea Bunhouse. He went towards Cremorne about 1850, and had some specialities in fruit trees; he also raised several good Pelargoniums. Extensive changes were made in this district, as also in Westminster, during 1851 and after, connected with the formation of Victoria Street, leading to the Abbey, which crossed the remnant of Tothill Fields and the green space round what was marked even on recent maps as Palmer's Village, Westminster. This street cut up as well what people called Elliott's Park, a demesne attached to the mansion of the proprietor of the Stag Brewery, from which at one time an avenue of old trees led to Palmer's Village and the artillery ground of historic fame. The grassy centre of Vincent Square is a fragment of Tothill Fields yet extant.—J. R. S. C.

DENDROBIUM ATRO-VIOACEUM.

THANKS to recent importations this beautiful species is now within the reach of all, and where there is heat at command should certainly be grown. The flowers are of long duration, lasting some thirteen or fourteen weeks, and the colours are so quaint and novel that they always command attention.

Having grown *D. atro-vioaceum* (fig. 16) successfully for some years, perhaps a few notes respecting its culture might be interesting. In the first place this species should be grown in the smallest pans possible, as it detests soil that is the least sour, but at the same time water must be given freely when in active growth, with less during the period of comparative inaction, though never allowing the compost to get very dry. The plant I find thrives well in a compost of one half best peat fibre, broken in lumps as large as walnuts, and nearly as much fresh green sphagnum moss, and must be potted moderately firm. They should be hung close to the glass, in a house that never goes much below 60° Fahr. In hot weather they must be carefully examined every now and then for red spider and thrips, which if allowed to get a foothold will soon injure the leaves and cause them to fall. This species I find likes a shady position in the house rather than a sunny one.—J. BARKER, *Hessle*.

CULTURE OF CALANTHE VEITCHI.

AS we grow *Calanthes* successfully here, I venture to forward a few remarks regarding their culture and an illustration of the house in which we grow them. The structure has a central path with a slanting stage on each side, these being covered with a groundwork of *Adiantum cuneatum* edged with *Panicum variegatum*. When the *Calanthes* are in flower we dispose them amongst the Ferns, and these by covering the pots and pseudo-bulbs, materially enhance the effect.

Calanthes, although simple to cultivate, are perhaps the best and most useful winter-flowering Orchids we possess, and the long time they keep in flower should induce cultivators to grow them far more extensively. I am surprised that florists and market gardeners do not turn their attention to the culture of *Calanthes*, especially those who have several houses devoted to Cucumber growing, as the conditions here requisite suit *Calanthes* admirably.

Our mainstay is *C. Veitchi*, as we consider it one of the best to grow in quantity. The bold habit of carrying the flower spikes, and their gracefully arching character, make it more suitable for decorating than any form of which I know, while the beautiful rose colour is very pleasing under the electric light. After flowering we give the bulbs a rest till they show signs of restarting into growth, when they are potted singly in 5 and 6-inch pots, with ample drainage, using nothing but good turfy loam as rough as we can procure, and a little dry cow manure. Great care is taken in watering till the pots are full of roots. Then we give them sufficient for their welfare in a tepid state, and when the bulbs have swelled a little and growth is active we give liquid manure about twice a week till the flower spike appears. After this clear water is reverted to, and if too much is given the pseudo-bulbs are apt to turn black and decay at the base.

By the above mode of culture our bulbs are from 10 to 12 inches in length, and the majority of them throw up two flower spikes from the base, and we have a few that have three spikes which, although not quite so large, are very useful.—W. K. PETTIGREW, *Hewell Grange Gardens, Worcestershire*.

[The photograph sent by our contributor conveys but a poor idea of the beauty of the combination he so ably advocates, and which we have more than once seen adopted. Unfortunately the picture is not suitable for reproduction.]

CYPRIPEDIUM ARTHURIANUM.

THIS is one of the most distinct and beautiful of the *C. Fairrieanum* crosses, which are now getting quite a numerous section. It was raised from the latter fine species and *C. insigne*, its parentage being easily seen in the hybrid itself, which has the drooping sepals of *C. Fairrieanum* with the colours mostly of *C. insigne*. Though not a particularly vigorous plant, it thrives well with ordinary care. The plants may be repotted in spring, spreading the roots out carefully as the work proceeds, and working the compost down among them, the latter consisting of good loam, a little peat, and some roughly chopped sphagnum moss, with abundance of crocks and charcoal. The pots used should be of medium size, for, as noted above, the habit is only

moderately vigorous, and the plants will not be satisfactory if stuck into the middle of a large pot.

Cypripediums differ from most Orchids in that water may be given immediately after repotting, the roots being of a stronger constitution than those of the majority of kinds, and delighting in ample moisture always. It may be grown in an intermediate temperature, or in any house where *C. insigne* thrives; but it is more easily checked than this old species, and this fact must not be lost sight of. It was raised in the nurseries of Messrs. J. Veitch & Sons, as was the pretty variety *C. A. pulchellum*.

ONCIDIUM CAVENDISHIANUM.

The fine handsome spikes of this species are now opening, the beautiful yellow tint being very clear and pretty. It is an easily

FIG. 16.—DENDROBIUM ATRO-VIOACEUM.

grown kind that should be in every collection, flowering at mid-winter and lasting an immense time in perfect order if care is taken not to wet the flowers. The roots are strong and vigorous, liking a very rough open compost and abundance of water all the year round. It likes an intermediate house and a good light position. It is a native of Guatemala, where it was discovered by Mr. G. Ure Skinner, and sent home to Mr. Bateman in 1835.—H. R. R.

BARK PRUNING.

THE objection of "W. S.," page 60, to ringing as a substitute for root-pruning, is simply that it would not cause the roots to become of a fibrous nature. He does not question or doubt the fruitful results accruing therefrom as recorded by the Editor, Mr. E. Luckhurst, and myself.

I think it will be admitted that luxuriant growth is invariably the outcome of large roots escaping from their intended sphere and penetrating into a strong subsoil. If, then, ringing, being resorted to, subdues the exuberance and causes fruitfulness, but does not result in the roots becoming more fibrous, it is evident that fibrous roots are not a *sine qua non* in fruit culture. The chief aim of the cultivator is not the production of fibrous roots, but of fine fruit in quantity. If the latter be obtained, why need he be anxious as to the form and location of the roots?

I do not wish to underrate the value attached to the fibrousness of roots, but I do say that if the roots become large and strong

thereby causing exuberance, it is far the better plan to use the simple and effective remedy of ringing, and allow the roots to remain as before.

There are, it is true, cases where only root-pruning will mend the grievance. If the subsoil, into which the roots have plunged, be of a wet stagnant nature through improper, or the absence of any drainage, it is evident that ringing would be utterly useless, but in the majority of cases I think it should supersede the laborious task of root-pruning, giving as it does equally good results at less cost.—W. R.

CHAFF AND GRAIN.

ERE the number for January 19th of the aged, but ever new, *Journal of Horticulture* is shelved in the gardener's home, or in the bothy, I would fain ask for it a second reading, particularly in the bothy. If second thoughts are best, second readings, like second siftings, oft disclose the grain amid the chaff. This number, methought, opened unusually chaffy. To the strains of "A Lost Chord" upsprang a "Fenn and a Fungus" in mortal combat. 'Twas grand to see the champion of Potatodom puffing anti-blight (through a bellows, I mean). No matter; he teaches some fine lessons to practical gardeners, and the lesson for the day as given out by him seems with sonorous sound to say, Work—work—work! That charming writer Mrs. S. C. Hall once said of a certain race, "Oh, if those people would only work instead of talking, how different they might be." Somehow life—a gardener's life—seems too short to overtake a tithe of the science meted out to us. And somehow, too, the pilots of "our Journal" seem inclined to guide us back into the old familiar channels. Perhaps, after all, there are fewer rocks and less wrecks in them.

Is there really a change in this direction? It looks like it. The very number of the Journal snipped from seems imbued with the spirit of common-sense teaching as opposed to scientific searching. It is almost—nay, quite—startling to find, on page 41, a chockful of science gardener chatting about "muck, handy lime, and tell-tale soot," and generally praising the blissful ignorant past. Note, young men, what Mr. Abbey says of "the good old times—8s. a week and bothy for a growing lad far on in the teens." But thereby hangs a tale. I will not, however, tell it, but the sequel is that 8s. then often went farther than 18s. now, although the bothy and the kitchen were a mile apart.

Turning over to page 48, "Soil Analysis," we reach (in the second paragraph) the "half-way house between exact science and rule-of-thumb." A very safe place, too, one thinks—for gardeners. Here men wearied with many things may rest in comparative security, and if threatened on the one side by advanced scientists, or on the other by those in the rear of elementary teaching, may say, "Let 'em all come," for this "half-way house"—the golden mean—is a tower of strength.

Again would I ask young Britons of bothydom not only to read their Journals, but to sift out the common-sense morals they convey. A grand one is, I think, easily discovered in the leader of the latest number to hand, "Life and Food," page 59. Under this simple heading that mysterious link between the two great kingdoms of life is more than hinted at. It is not a chaffy subject, but, although heavy with chemical constituents and saturated with science, intensely interesting. Without courting mental dyspepsia a modest sampling is able to yield foretastes of the pleasure and profit in store for those who come to regard the objects of their care as living, breathing subjects, demanding due recognition as such from thinking heads and ministering hands. Granted this, then more work is merged in a labour of love conducive to the best results.

It is not easy to describe the subtle influence of the love of gardening. It may be noticed, however, that some plants in particular seem "uncertain, coy, and hard to please." This arises from their character being misunderstood; yet some few are able to woo them into health, happiness, and beauty. Witness those grand specimen plants and grand specimen gardeners of the past, aye, and of the present too. Some of them were, and some of them are still, terribly deficient in revealed science, but, judging by results obtained, what they lacked in that direction was more than made up for by that love which amounts to a passion reciprocated, in the silent life of their subjects. One such I knew who was rarely beaten with his twelve stove and greenhouse plants. He worshipped them, and though his knowledge of book science was nil, mentally analysed them and knew their wants better than any chemist could tell him. Science may surpass the old miracles of faith, but it will never supplant intuitive love, and one questions still if it has even shaken the great "muck" doctrine.—WATCHMAN.

WEATHER IN LONDON.—The frost, which remained with us from Wednesday until Saturday last, appeared to meet with general appreciation. It was not very severe on any morning, but still water was thinly coated over on Friday. During Saturday the coming change could be felt, and Sunday was a thoroughly wet and dull day. The rain hardly ceased until evening, and then only for a very short time. Monday opened wet, but became dry and colder later, followed by frost in the early hours of Tuesday morning. Wednesday, like the preceding, was dull, foggy at times, and cold.

— WEATHER IN THE NORTH.—The prolonged course of rainy weather has been followed by a week of pretty keen frost. From the 23rd ult. to 28th from 13° to 17° were daily registered. On Sunday, and again on Monday afternoon, there was some appearance of a change to milder weather.—B. D., *S. Perthshire*.

— "SINGLE-HANDED" GARDENERS.—At our show we have a class for "single-handed" gardeners. The regulation reads as follows:—"A single-handed gardener is a man without regular assistance." It is a source of endless trouble to the Committee to decide questions as to when a man ceases to be eligible for this class. Will some brother secretary help me with his experience to define a "single-handed gardener?"—T. W. THORNTON, *Beckenham Horticultural Society*.

— PRESENTATION TO MR. J. CARRUTHERS.—Mr. James Carruthers, lately gardener at Hillwood, Corstorphine, has recently been the recipient of a present from his friends to show their appreciation of his services to horticulture, and the high esteem in which he was held. This was supplemented by a contribution from the Scottish Horticultural Association. A small deputation of subscribers, headed by Mr. R. W. E. Murray and Mr. M. Todd, waited on Mr. Carruthers, at Ravelston, where he has acquired a business, and presented him in name of the subscribers with a cheque for over £60. Mr. Todd happily expressed the great pleasure it gave the subscribers to show their hearty goodwill towards him, congratulated him on his improving health, and expressed the warmest wish of his many friends that his strength and activity would return, and that great success would attend his new business venture. Mr. Carruthers replied in a few brief remarks.

— HANLEY FÊTE.—We have been favoured with advance proofs of the schedule of the Horticultural Fête that is to be held at this Staffordshire town on Wednesday and Thursday, July 5th and 6th. The prize list and the rules governing exhibitors are very comprehensive, and it will be scarcely possible, after a careful perusal of the latter, for anyone to get on the wrong track. Slightly over 100 classes are embodied in the list, these being divided into sections that are open to all, open to gardeners and amateurs, and open to cottagers only. Several of the leading firms offer prizes for various products, and these of course are subject to the customary stipulations. The Society will give many liberal prizes in several classes, notably £70 for a group of plants; £30 for a group of Orchids; £22 10s. for twelve specimen plants; £12 for eight exotic Orchids; £15 for forty-eight Roses; £13 for thirty-six Roses; and £22 for a floral display, with numerous others. The Secretary is Mr. J. Kent, The Park, Hanley, from whom full particulars may be had.

— DECORATING FRUIT EXHIBITS AT FLOWER SHOWS.—Discussions have been heard of late as to whether exhibits in fruit classes should be enlivened by floral decorations or not. At some shows I have found it difficult to distinguish one entry from another because the exhibits were so massed together; so confusing, one had to stop and consider which was one entry and which was another, and so on. I think they ought to be a little more distinct in arrangement than they sometimes are. At Chrysanthemum shows some societies offer a prize for a specimen Palm, and we do not usually find the exhibits massed in a corner or other similar space, but distributed where their presence is more needed and effective. In decorative classes, such as for epergnes and vases, the exhibits are often quite spoilt by being so crowded together; and I would suggest that if these epergnes and vases could be disposed at intervals between collections of fruit, the effect would be far greater, and the fruit tables not seem so monotonous, while judges would be aided in making their awards to the decorative exhibits.—R. H. JEFFERY, *Nursling, Southampton*.

— **THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—The sixtieth anniversary festival dinner of this Institution will be held at the Hôtel Métropole on Wednesday, June 28th, under the presidency of the Rt. Hon. Earl of Derby, K.G., and not on July 28th, as stated on page 71 of our last issue.

— **GARDENING APPOINTMENTS.**—Mr. James Threlfall, for many years in the Gardens, Swanmore Park, Bishop's Waltham, has entered upon his duties as head gardener to Colonel R. Pilkington, M.P., Rainford Hall, St. Helen's, Lancashire, where no doubt the experience gained under Mr. E. Molyneux will stand him in good stead. Mr. A. G. Nichols, for more than eleven years gardener at Nuneham Park, Abingdon, has succeeded Mr. Turton at Maiden Erleigh, Reading.

— **THE IMPORT TRADE IN POTATOES.**—Potatoes to the value of £1,913,912 were imported into Great Britain last year. Of this sum £547,000 went to the Channel Islands, £457,000 to France, and £470,000 to Germany. The most remarkable feature of this import trade in Potatoes is the great development which has taken place in the exports from Germany. Last year, as just stated, over £420,000 worth were exported from that country to Great Britain, though in 1897 the value of the exports amounted only to £67,907, and in 1896 to the merely nominal sum of £3208.

— **ANEMONE BLANDA.**—This is the earliest of all the Anemones in coming into flower, and often opens before Christmas. Like many others of the early flowers it is not so forward as usual this season, and the first blooms were out on January 17th. It continues to give a succession of flowers for several weeks, these varying through all shades from white to the darkest blue when raised from seed, but may be kept true to colour by division of the roots. Both *A. blanda* and *A. fulgens* are subject to decay if left more than two seasons in the same position, and it is best to lift them when the foliage withers, and dry the roots on a shelf. They may be broken up and replanted, in ground that has been previously manured and dug, early in August; if kept longer in a dry state the roots are weakened, and the flowers will be smaller in consequence.—W. H. DIVERS.

— **LIVERPOOL HORTICULTURAL ASSOCIATION.**—On Saturday evening the twentieth annual general meeting of the above Association was held. The financial statement showed a balance in hand of some £80. The Lord Mayor, Wm. Oulton, Esq., was nominated as President for the year: Mr. Thos. Foster, Chairman; Messrs. Harwood, Banner & Sons, and Mr. R. G. Waterman, Auditors. Mr. W. Dickson, who has held the post of Secretary for a number of years, was obliged to resign owing to ill-health, and Mr. Sadler, his partner, was elected to fill the position. The Committee was also elected. A movement is on foot for the Society to try to amalgamate with the Royal Lancashire Agricultural Society, which is to hold its show in Liverpool this year, and for which great preparations are being made, but negotiations are not completed. It was unanimously resolved to vote 3 guineas to the Gardeners' Royal Benevolent Institution, and a sum of 2 guineas to the Royal Gardeners' Orphan Fund. The usual votes of thanks terminated the meeting.—R. P. R.

— **ROYAL BOTANIC SOCIETY OF LONDON.**—The first of a course of lectures on seed-testing, with demonstrations, was given Monday last in the lecture room of the Society at the Gardens, Regent's Park, by Mr. D. Finlayson. The lecturer deplored the fact that while all over the Continent and in America seed-testing stations under Government control had been established, where farmers and agriculturists could have their seeds tested, and obtain statistics and information, in England, where the need was greatest, these questions were left to a few private persons, or one or two societies, whose researches were limited to their own members. Considering how great was the annual loss to agriculture in this country on account of seed adulteration, the selling of seed which, owing to age or other causes, has lost its vitality, and the mischief done by noxious weeds sown with it, and how inefficient were the means for detection possessed by farmers and others, it was a matter of surprise that the question of public testing stations had not been more generally taken up. The lecturer gave three simple rules—first, that good varieties only should be purchased; secondly, that the heavier it was in comparison with its bulk the more likely it was to germinate; and thirdly, that the impurities should be carefully studied. Bits of dirt and debris were of far less consequence than the minute seeds of weeds. He instanced one apparently clean sample he had tested, which contained enough weeds to produce over 5000 of the worst kind for every acre sown. The lectures are to be continued every Monday afternoon to March 27th. [We fully believe that seeds as sound, clean, pure, and good are supplied by British firms of high repute as any that are sold on the Continent, and we suspect cheap rubbish is to be had abroad as well as at home.]

— **ROYAL GARDENERS' ORPHAN FUND.**—The annual general meeting of the subscribers to this Fund will be held at Anderton's Hotel, Fleet Street, London, E.C., on Friday, February 17th, for the purpose of receiving the report of the Committee and the accounts for the past year; to elect officers for the ensuing year; to elect nine children to the benefits of the Fund, and to make certain alterations in the rules. The chair will be taken at three o'clock. The poll will close at 4.30 P.M., after which no votes will be received.

— **HORSERADISH.**—It is a good plan to replant a plot of Horseradish each season, and the earlier this is done the better. Straight pieces of root about a foot long with a single crown attached to each, and all the roots rubbed off with the exception of a few at the base, form the best material for planting. The soil should be deeply dug, but not manured except at the base into which the roots can pass. Plant these pieces a foot apart, placing them straight down in deep holes made with a dibber, and press the soil round them. Keep the ground clear from weeds throughout the summer, water if necessary, and in the autumn the roots will be fit to dig.—E. D. S.

— **TRAPPING BULLFINCHES.**—On page 494, December 29th, 1898, in "Notes and Gleanings," Mr. James Hiam kindly gives "C. N." "information on trapping bullfinches." As I have caught birds and killed them I can hardly be hard on Mr. Hiam, but I am quite sure I will never do it again. Sparrows, perhaps, might be trapped because very numerous, mischievous, and good for food, but our beautiful song birds and lovely plumaged birds never. We need them to sing and trill, to adorn and cheer our beautiful hills and dales, and woods and lanes. Let Mr. Hiam tell his inquirers to mix soot and lime, adding a wineglass of petroleum to every gallon, syringe his trees, and he will not lose many buds. Renew as needed.—AVIS.

— **MR. EDWARD OWEN GREENING.**—This gentleman, as is widely known, is the Secretary of the Agricultural and Horticultural Association, and the moving spirit of the great co-operative shows which are annually held at the Crystal Palace. He is imbued with a deep love of gardening, and through his agency many workers in various handicrafts have been induced to practise it who would otherwise have been left outside the fold. All this contributes to the general good, because when a multitude of persons are induced to begin gardening, and who derive satisfaction from it, there is no knowing where they will end. Mr. Greening is a man of great enterprise, and has by a happy conception obtained expressions of opinion on gardening from celebrities in other walks of life, such as H. Rider Haggard, Dean Bradley, Miss Braddon, Mrs. Fawcett, Charles Booth, Sir John Lubbock, "Ian MacLaren," Dean Hole and many others, whose portraits and appreciations he publishes in his annual "One and All Gardening." He has also the co-operation of his practical friends Mr. D. T. Fish and T. W. Sanders, who are equal to the treatment of all gardening subjects, useful and ornamental. Among the copious illustrations the greatest novelties are those employed in the potting of plants, which in their way are unique and striking objects of resourcefulness.

— **THE 1866 INTERNATIONAL SHOW COMMITTEE.**—By the recent death of that fine old veteran and illustrious horticulturist, Mr. John Lee, the now comparatively few survivors of the executive of that long to be remembered event, the Great International Exhibition of 1866, are materially reduced. I believe of those remaining there are but Mr. W. Paul, Mr. W. Bull, Dr. Masters, Mr. H. J. Veitch, Sir D. Cooper, and Mr. R. Dean. Thirty-three years is a large slice taken out of any man's lifetime, and in 1866 the late John Lee was sixty-one years of age, the leading spirit of one of England's great nurseries and a horticulturist of world-wide reputation. To have remembered him when some recent honours were distributed would have been an act of excellence; but he, like some other illustrious greybeards, was overlooked. We have not so many John Lees in horticulture that we can afford to ignore them. Somehow the enterprise shown by the old ones thirty-three years ago seems to be lacking now, for no one has the courage to promote—and here, too, in the greatest and foremost gardening country in the world—another great international exhibition. They can do these things abroad, but we do not now. More's the pity. How fittingly could we next year celebrate the close of the nineteenth century, the most wonderful century of years in history for horticulture, for how marvellously has gardening developed in that time! Those who are young may live to see great things in the twentieth century, but they can hardly see greater relative progress than the end of the nineteenth century has produced. Not a few of the old ones in horticulture would like to see one more great international show before they pass away. It may be added that, in addition to those named on page 63, Mr. Owen Thomas was present at Mr. Lee's interment.—WANDERER.

— **RICHMOND HORTICULTURAL SOCIETY.**—We are requested to state that the twenty-fifth annual Exhibition of this Society has been fixed for Wednesday, 28th June, 1899, in the Old Deer Park, Richmond. The Secretary is Mr. C. R. King, George Street, Richmond, Surrey.

— **A GARDENER'S ALMANAC.**—Mr. S. Heaton, the energetic Secretary of the Isle of Wight Gardeners' Association, has sent us a copy of the Society's Almanac for 1899. It is a most creditable production, combining the artistic and the useful in the best degree. In size it is about 3 feet 4 inches in depth by 2 feet in width, and the whole of the sheet is covered with calendrical notes, tables, postal information, lists of members, and other matter of horticultural interest.

— **COTONEASTER MICROPHYLLA.**—What a splendid plant this is for the winter decoration of walls, banks, and rustic fences. Covering the whole of the south front of a neighbouring cottage is a magnificent specimen, fully 12 feet high, and loaded with its attractive berries. The warmth derived from the wall no doubt has much to do with its freedom of fruit production. Be that as it may, this evergreen might with advantage be much more freely employed for such a position than it seems to be at present.—E. M.

— **THE FROST.**—The recent spell of moderate frost has been serviceable in solidifying sap, and holding what threatened to be precocious leaf and flower development in useful check. But still little of good will have been done if followed at once by a mild forcing variation. We need such weather as was the frost for a month at least, and that would then leave us on the margin of March, when with more sunlight and prolonged days much useful garden work may be done. The spell of frost has enabled much moving of manure and other soil dressings to be done freely without harming the soil or garden paths. It has helped the work of tree pruning where neglected, and it has specially facilitated the collection of leaves for storing and decaying where too much moisture has been in the way. Altogether we are getting an ideal winter.—D.

— **OUTDOOR VIOLETS.**—Owing to the extremely mild season experienced up to the present there has been no lack of these sweet flowers, which are always welcome. At the time of writing established plants of The Czar, growing under the protection of a fruit wall, are throwing up an abundance of flower, and though the stems are yet short, they are none the less appreciated. It is not everyone who has the facilities for growing Violets in frames, and in the absence of such greater store is set on the outdoor blooms. There are few gardens which do not possess sheltered nooks and corners suitable for the reception of such varieties as Princess of Wales and the old favourite mentioned above. When warm spring days appear they flower profusely, and the blooms which are obtained now seem all the sweeter and more pleasing because they come a little before the orthodox time.—H.

— **FLOWERS AND VEGETABLES IN TIBET.**—Messrs. James Carter & Co. write from 237, High Holborn:—"Although many parts of this enormous Central Asian territory have not yet been trodden by Europeans, it may interest you to know that we have a lady customer at Yatong—the only British resident, we believe, in that city—who possesses a garden and grows vegetables and flowers. Her communications reach us with regularity via Darjiling. Quite recently we have received a report upon the value and adaptability of these products in that climate, 10,000 feet above the level of the sea, where snow falls sometimes in May and begins again in October. Amongst the information given we are told that Tomatoes produce flowers but no fruit, Onions decline to form a bulb; Cabbage, Carrot, Turnip, and Mustard and Cress are excellent. Peas are good at certain times. Nearly all our common garden flowers proved a success."

— **SCHOOL CHILDREN'S HERBARIA.**—Of the premiums offered for herbaria to the school children of Hartford, Connecticut, Mrs. Seliger says, in "Meehan's Monthly":—"We have had our herbarium exhibition of what the school children brought together. It was the centre of attraction at the Chrysanthemum Show, and a more pleasing feature one cannot well imagine. Notably perfect was the arrangement of displaying the flower sheets on double screens, hooked together and standing free, with a passage between the rows. This showed to great advantage the specimen collected. About 6000 of such had been sent in for the contest. All of them had some merit of more or less degree, and considering this is the first occasion that this has been set in motion it was a grand success. Many visitors were surprised that we have so many native flowers, but you know the least and often most noxious weeds make the prettiest specimens for herbaria, while bright and showy flowers mostly show to disadvantage on account of having lost their colours."

— **PROTECTING CELERY FROM FROST.**—Frost and damp combined are injurious to Celery at this period, and some simple but effectual means must be provided in order to protect the plants which remain in the ground. Covering with litter may serve a temporary purpose, but it is not sufficiently reliable as a complete protection except for the soil. The best plan is to nail two boards together and invert over the plants, using litter for the ridge below. This covering may be easily removed and readily replaced.—S.

— **LAWNS OLD AND NEW.**—If this had been the title of a well printed and illustrated manual just issued by Messrs. James Carter & Co., few persons would have disputed its appropriateness. However, though the actual title is somewhat more diffuse, it is not less expressive of the matter over some twenty pages. This pertains to the formation and renovation of lawns for various purposes and grassy grounds generally. The information is clear, concise, and practical, evidently the outcome of successful experience, and the details may be followed with advantage in carrying out the lawn work described.

— **ASPARAGUS.**—In making a new plantation of Asparagus from seedling plants, whether in single rows or in beds, it is advisable to grow the plants two years before finally planting them for the purpose of separating the male from the female roots. It may not be generally known that the male plants throw up a much larger per-centage of stalks, and therefore are the more desirable. In testing the roots for this purpose all those that bear seed berries the second year should be discarded. If the plants are put out in rows 3 feet wide, taking out a trench 9 inches deep, the soil can be thrown into a ridge down the centre upon which some summer crop may be grown. The soil can be employed annually for blanching the Asparagus heads where this form of production is appreciated. The trenches, too, afford ample scope for watering the roots with liquid manure to assist vigorous growth.—E. MOLYNEUX.

— **MARGUERITE CARNATIONS.**—I notice Mr. A. Outram, in his notes on Luton Hoo Park on page 30, speaks of the Marguerite Carnations, lifted from the open ground, that he saw in flower there. It is questionable whether the usefulness of this class of Carnations is fully appreciated for providing bright flowers at a dull time of the year. Not only are they useful when lifted in the way described by your correspondent, but also when grown entirely as greenhouse plants. A method followed successfully by the writer was that of sowing in shallow pans early in March and allowing the seeds to germinate on a shelf in a warm pit. The first potting was into 4-inch pots, growing the plants near the light in a cool compartment. Subsequent shifts were given till the plants were in 6-inch pots, in which size they flowered. A cold frame or a sheltered position outdoors is suitable for the plants during the summer, and in the autumn and winter they make a bright show in the greenhouse and conservatory. There is generally a percentage of single flowers, but this is only small if the strain from which the seeds are obtained is a good one. The lateness of the flowering season is a drawback to growing Marguerite Carnations outdoors, but if plants well studded with buds are lifted in the autumn without unduly disturbing the balls of soil, and placed in pots large enough for their reception, they will produce an abundance of bloom during the winter, as in the case of the plants at Luton Hoo.—G. H. H.

— **CONDITION OF THE SOIL.**—It is very interesting to find that almost everywhere, in spite of our having so far had a very rainy winter, the soil is in a good working condition. The recent spell of frost, and with it drying east wind, has done wonders in improving the surface, and would the dryness but endure for a week or two, it would be very possible to sow early hardy seeds under admirable conditions. Not that I encourage too early sowing of seeds, the resultant plants of which may suffer from later cold, but often when the ground is in a very favourable condition, sowings made early turn out better than later ones, made when perhaps the soil is too wet, and working and treading cause it to become clinging and hard. He is a wise gardener who makes the most of favourable opportunities, and in the winter these may not occur too often. I have taken stock of the country places, the roadsides and ditches in many directions just recently, and in spite of our having had such heavy rainfalls, have noticed how rapidly the water has passed away. That shows that the lower subsoils are yet far from being saturated. I have seen very diverse evidence of the rainfall in some previous walks, when water has been seen almost everywhere. Now it is only in the river or stream bottoms that there is any material evidence of its presence, and even then a dry day or two reduces these evidences greatly. During February we ought to have very much rain, yet if the soil's requirements are to be fully met, should we now have a dry spring, as surely there will be a cry for more rain very early in the summer.—CULTIVATOR.

— FRENCH BEAN, EMPEROR WILLIAM. — Having tried the above Bean for the first time last season, I can confidently say that we have in it a valuable addition to our list of French Beans, and one perfectly distinct in every way. It belongs to the white-seeded varieties, the somewhat irregular pods being conspicuous. The crop was immense, and was ready for use earlier than other varieties sown at the same time. The flavour was of the best, but the chief features seem to be its continuance in cropping, not quick to become stringy, and its admirable forcing properties. It is well worth a trial in every garden. — R. P. R.

— SCIODOPITYS VERTICILLATA. — In the interesting description of Hafodunos and its collection of Conifers (page 46), I note that special mention is made of the unusual cone-producing proclivity of this unique Japanese species, and I thought it would be additionally instructive to learn if there are other specimens in the United Kingdom exceeding it both in size and fruition. Probably, however, a specimen, which I believe is growing at Castlewella, co. Down, Ireland, may have by this time attained to similar dimensions, as some five or six years ago it was recorded as then being about 10 feet high. — W. G.

— MURRAM GRASS. — A very successful experiment has been made by the South Australian Government in the planting of Murram Grass on the sand hills at Normanville, which is the seaport of the large and fruitful district of Yankalilla. The Murram Grass, which was brought into requisition for the purpose of binding and consolidating the sand, is described as serving its purpose admirably. We notice, says "Indian Gardening," that an attempt was made last year to grow this Grass on the Government estate at Pooree, in Orissa, from roots received from Australia, but the roots were dry on receipt, and the experiment failed. Further action, we are told, is now being taken to try and grow this Grass from seed.

— COLEUS THYRSOIDEUS. — This is a new plant from British Central Africa, and from the way it has behaved, so far, it is likely to become a popular winter-flowering greenhouse plant in the near future. It differs from the garden Coleus by being of no service as a foliage plant. The leaves are more or less cordate, green, and deeply serrated. The flowers are bright blue, and produced in upright, terminal panicles from each branch. It should be grown cool all the summer, the same cultivation as that given to Salvias being suitable. Cuttings rooted in March make fine plants 2½ feet across in 8-inch pots for the following winter. The temperature of a warm greenhouse is necessary for flowering. It can be seen in flower in the Begonia house and Mexican house at Kew. — D.

— RENEWING OLD SEED. — Very interesting experiments are being conducted at the Amherst (Mass.) experiment station in bringing to more active life seeds which are too old to sprout well. Nothing has been published on the matter as yet, but the "American Agriculturist" has ascertained that old seeds have been treated with a 2 per cent. solution of asparagin, a vegetable extract obtained from German chemists, and the result has been to increase the germinating power greatly. Seed which before treatment showed only 50 per cent. of germination with one-half worthless, after treatment showed 98 per cent. of germination and only 2 per cent. which failed to sprout. Since asparagin at present costs 1 dol. 50c. per ounce, the method is not profitable for ordinary seeds. But seeds of new varieties and certain flower seeds which are actually quoted at more than their weight in gold might be treated in this way with profit. Experimenters are in hopes of finding a cheaper substance or a cheaper way of making this article for treating the seeds.

— BEGONIA HAAGEANA. — Among the shrubby species of Begonia this is certainly one of the best. It combines the merits of being decidedly ornamental, whether taken from a foliage or flowering point of view, has a first-rate constitution, and is easily managed. It was introduced from Brazil about a dozen years ago, and distributed by Messrs. Haage and Schmidt of Erfurt. If allowed freedom of growth it makes a dense bush 4 or 5 feet high, and 3 or more feet in diameter. The leaves vary from 6 to 12 inches in length. They are dark green above, reddish underneath, and thickly covered with hairs on both surfaces. The flowers are white with numerous red hairs about the lower half of the petals, and about 2 inches across. They are produced in large, drooping, cymose heads, often a foot across, and last in good condition for several weeks. It is rarely a large plant without flowers, but probably it is at its best in midwinter. It succeeds well either as a pot plant or planted in a border; in either case it will continue to grow and flower for several years without becoming lanky, a thing which many of the other species will not do. A house with a minimum temperature of from 48° to 50° is suitable for it. — W. D.

— HESSLE GARDENERS' SOCIETY. — At a meeting of the above Society, held in the Parish Schoolroom on January the 24th, Mr. F. Mason presiding, Mr. J. Stow, Hessele, read a paper entitled "Fruits and their Flavours." The essayist dealt with the different fruits which are used for essence making, describing the manner and the way the different essential oil and flavours are abstracted. The essay, which proved to be most instructive and interesting, was much enjoyed by the numerous members present, and there was a capital discussion. The usual vote of thanks was passed to the essayist and the Chairman. — J. T. B., Hessele.

— MEYENIAS. — What a pleasure it was to me to see that short but admirable note in your issue of last week on the beautiful though somewhat neglected Meyenias, and the capital illustration of what I consider one of the best varieties. I well remember it, as I think it was quite the first plant that I saw in flower when starting my gardening career, and I have a vivid recollection of the impression the handsome shades of purple and yellow of the flower made upon me, and how choice they looked dotted amongst other stove plants. Would that it was oftener seen now. The cultural details are so good as to make comment unnecessary. The dictionary says that it was introduced from West Africa in 1857. — R. P. R.

— EARLY CAULIFLOWERS. — Tender heads of Cauliflowers are always acceptable, and a sowing of a good early variety, such as Early Snowball, made in moderate heat in January or February, will give good results later on. The seeds must be dispersed thinly, and when the young plants commence to show themselves, remove the box to a light position close to the glass. When the young plants are large enough for removal, they should be pricked off into boxes of old potting soil, with which has been incorporated a little Mushroom bed-refuse. By the use of the manure the plants will lift with good balls, and after slowly hardening, they will be in good condition for removal to a warm border at the end of April or early in May. — V. T.

— LICHENS AND FUNGI. — I had the pleasure of enjoying the hospitality and a couple of hours' conversation a few days since, of the Rev. Mr. Dean, a namesake only, who is the Congregational minister at Gomshall, near Dorking, and resides at Abinger, where he acts as the local manager of the Technical Education Lectures, and is a member of the Parish Council, he is also a F.R.H.S. He further, having strong gardening instincts, superintends a number of small gardens worked by both boys and girls, receiving for this purpose the liberal support of Lord and Lady Farrer. Mr. Dean was in his young days a gardener, but preferred to enter the ministry. Living in a district peculiarly rich in native flora, he is a pretty good botanist, and has a wide knowledge of wild flowers. He was enabled to interest me immensely when at his house, by showing, with the aid of a powerful microscope, minute portions of moss, lichen, fungi, and other of Nature's small productions of the most wonderful and beautiful kind. Concerning these things, the gardeners' minister possesses very wide and interesting knowledge. — A. DEAN.

THE ORPHAN FUND SECRETARYSHIP.

It will be a sad misfortune for the orphans of gardeners should the coming election, on February 17th, lead to any such contest between gardeners and the trade as that indicated as possible in the *Journal of Horticulture* by "A. D.," page 72. It is hoped that the good sense and brotherly spirit of the Committee and all concerned, as well as the numerous and united support of true gardeners, will prevent this most useful Fund from suffering loss through rival interests or high-handed modes of electing a successor to Mr. Barron, who has managed the Orphan Fund so smoothly and successfully since its establishment.

The loss of the services of the present Secretary through ill health, if they must be lost, will create a crisis in the history of this useful Society, and it will be unworthy of the wisdom, gentleness, and courtesy of gardeners should this mode and form of election be allowed to create others. All of these difficulties might have been steered clear of for the present had my suggestion made in several of the gardening papers been adopted. These were in brief, that Mr. Barron's resignation be refused, and a holiday and assistance offered to enable him to resume and continue his distinguished and splendid services for our orphans, which all true gardeners, whether in the trade or not, have so highly appreciated.

It is a long cry from Edinburgh to London, and I fear I shall not be able to be there on February 17th; but could I be present I should exhaust the forms of procedure in endeavouring to keep our present Secretary, after a rest and with help if needful, before electing a new one. But should this, which seems far the best for our orphans and all concerned, prove impossible, then there is no doubt that the common sense and sound judgment of the subscribers present will proceed to elect the best man for the office without regard to sectional or personal interests. — D. T. FISH, 12, Fettes Row, Edinburgh.

SELAGINELLAS AND THEIR USES.

THE many beautiful species and varieties of these evergreen plants include some of the most diminutive forms of vegetation which are cultivated for ornamental purposes, and, like the animal forms of Nature's lilliputians, there are times when they prove of the utmost service. A house devoted entirely to Selaginellas might be made attractive at all times, as a varied collection would supply ample diversity of form and colour; but it is not, perhaps, when turned to account in this way that they would be the most useful in the majority of gardens, but rather when associated with other plants; in some instances for clothing the soil in which pot plants are growing, in others for forming an edging or groundwork to conservatory beds or borders, as well as in the infinite variety of ways in which the decorator can make good use of them.

Small Ferns, placed in china pots or other ornamental receptacles of various sizes, are now largely employed in house decoration. If these are given a groundwork of *Selaginella apoda* or *denticulata aurea* how pretty and finished they look!—tasty little ornaments worthy of finding a place in any boudoir or drawing-room. Tulips, Daffodils, Lily of the Valley, and Hyacinths are at the present time the principal flowers at command for dinner-table decoration. If these are arranged in shallow bowls, or on thick pieces of brown paper cut into any required shape, with *Lycopodium denticulatum* forming a groundwork, a few trails of *S. caesia* laid upon the cloth, and small specimens of *S. Martensi variegata* used as "dot" plants, a pretty and characteristic effect may be produced which would be hard to beat in the depth of winter. Dinner tables are made much handsomer than formerly, and where plants of Selaginellas are grown ample material could easily be obtained to cover the whole available surface of the table with them, the outline being fashioned in flowing curves, with mounds raised at suitable points surmounted by graceful foliaged plants. *Denticulata* would here again be the most suitable for forming the groundwork, and some of the upright growing variegated species could be introduced at irregular intervals; then if scarlet Tulips were arranged in masses and little groups, with chains and waving lines of the same flowers connecting the masses in some instances, in others forming broken lines between, we should form a pleasing picture of Tulips as seen in the wild garden springing from a carpet of the rich greenery of spring.

The above brief illustrations are simply intended to show a few of the many ways in which these lovely evergreen plants may be used with effect, and also with the object of perhaps stirring the imagination of some Journal readers sufficiently to cause them to set about the work of propagating a good stock of Selaginellas, as I know from experience that when decorations on a large scale are continually being carried out, one is often inclined to lament the fact that efforts were not previously made to work up a sufficient stock of such useful material. Those who are in such a dilemma at the present time cannot do better than begin propagating at once to secure immunity from similar inconvenience in the future.

Fortunately nearly all the Selaginellas are very easily propagated. When plenty of close frames are at command in the propagating house the cuttings may be rooted very quickly, but during the spring months such frames are generally required for the immense number of plants which do not succeed well unless kept close for a time. Having often been pressed for room of this description, I have been led to adopt another plan for raising Selaginellas which I find answers equally well, the only difference being that the cuttings do not root quite so quickly. In nearly all houses, especially if they are old, a comparatively shady corner can be found; this is just the place for the raising the plants under notice.

We have a Fern house, one end of which is somewhat darkened by a building at the back, and when a large number of Ferns has been potted, those placed in this position never, even in the summer, make such satisfactory progress as those in other parts of the house. I now devote this space entirely to Selaginellas, and find they succeed admirably. The cuttings are made in the ordinary way, from the creeping stems; these are inserted thickly in pots, almost half filled with drainage. Light sandy soil is used, with a little rough peat over the corks. After being arranged in the house on a stage with an ashed bottom a thorough watering is given, and daily syringing is practised. At this season no shading is given, but during the summer months sheets of paper are laid over the cuttings. With such treatment very satisfactory results are obtained, and a comparatively useless part of a house for other purposes turned to good account.

The following species and varieties include most of the best in commerce, and are all worth growing:—*albo-nitens*, dwarf trailing, leaves streaked with white; *argentea* (silvery) pretty, and useful for small pots; *atro-viridis*, rather erect in habit of growth, sometimes attains a height of 1 foot; *Brauni*, erect growing, stems 1 foot in length, of a soft yellow colour; *caesia*, beautiful for baskets, or for planting in pockets on the walls of a fernery, as the trailing shoots attain a considerable length, and are of a peculiar blue shade of colour;

conferta, dwarf, trailing; *denticulata*, and *d. variegata*, two well known gems, largely used for edgings, and covering the soil in which pot plants are growing; *plumosa*, *Griffithi*, *involuta variegata*, a beautiful tufted variety, with wiry-like drooping stems; *Lyalli*; *Martensi*, a well known greenhouse species, erect in habit of growth, and a good grower; the stems sometimes attain a height of 1 foot; the variegated form is exceedingly attractive for arranging in a fernery; *patula pilifera* *Vogeli*, a well known stove species, which produces stems from 1 to 2 feet in length, these are often tinted with pink. There is also a variegated form which is highly attractive, and *Wildenovi*. This is a useful stove climber, which is not often met with now, although it was a favourite some years ago. It requires plenty of syringing to keep it free from insects.—H. D.

A COMMON ERROR.

THERE can, I think, be no doubt that we have long pursued the practice of training many plants and trees grown in houses too close to the glass. We see it frequently in the case of Vines, Peaches, and Figs, with the result that the greatest difficulty is experienced in keeping red spider and other insects in check, when the general treatment is such that there ought to be no difficulty in the matter. The wonder is that we often succeed as well as we do, seeing how terribly high the temperature is just under the glass in very bright weather, and how rapidly it changes during cold nights.

Mr. W. Taylor showed us long ago the advantages of training Vines a few feet, instead of inches, from the glass, for the Vines on which he grew his marvellous Muscats at Longleat years ago were at the extremities of the rods 5 or 6 feet from the roof. Many good fruit growers, who at various times visited Longleat, saw the advantage of the plan, and modified their practice as far as circumstances allowed in houses already existing, and in others constructed under their directions fixed the trellises 18 inches or 2 feet from the glass, with improved results. It is, however, to be regretted that the practice is not more generally followed, because it is a great step toward making Grape growing easy, as keeping the leaves clear of red spider is yet one of the most troublesome matters connected with Grape culture.

Some may advance as an objection to the plan that where it is followed the houses must necessarily be built more lofty, but the front stages in vineries might often be made a little lower without inconvenience, and in vineries little used for plant growing the above objection would not apply. Another point to be considered is that the front of a lean-to or the sides of a span-roofed house are just the places where for convenience the trellis may be closer to the glass than under other parts of the roof, because the morning atmosphere as it becomes heated rises to the apex of a house. If, then, we fix our trellises 15 inches from the glass at the front, and allow from 2 to 3 feet at the top, we make a compromise which is satisfactory from every point of view. With Roses, again, we may often see the evil effects of training too close to the glass—persistent attacks of mildew and green aphid; young growth and flower buds pushing against the glass and being damaged, are all the evil results of the system. When Roses are trained to the roof of a conservatory or greenhouse there is generally plenty of head room to allow the trellis to be fixed 15 inches from the roof, and this distance would suffice.

There are, however, other instances in which such a space could not be allowed. As an example, let me give that of a house I have lately dealt with. This is a low span-roofed structure with Tea Roses planted in beds on each side and trained to the roof, the wires being fixed only 8 inches from it. Throughout last summer these Rose trees were a constant source of annoyance, as the shoots were continuously pressing against the glass. Many Rose buds were deformed in consequence, and the money spent in insecticides to keep the trees clean was double what it should have been. A few weeks ago this house was overhauled, the trees were pruned, borders dressed, and a new trellis fixed, not from the roof, but from the ground. Stakes were driven into the border 4 feet apart. Strong wires stretched the length of the house and fastened to them so as to form a convex surface, a foot from the glass at the sides of the house, and 4 or 5 feet from the apex. At intervals of 5 feet a strong shoot was taken from this trellis and fastened up to the roof, not with the object of training them any further, but in time to form, as it were, pillars on each side of the central walk. The trees so treated broke strongly, are now growing freely, and I look forward to securing far better results this season, with less trouble to boot.

By the time these notes appear in print many will perhaps be engaged in pruning and retying Roses in late houses, and in some instances may find it to their advantage to adopt the plan above outlined, or to modify it according to the circumstances of their own cases.—OBSERVER.

CAMELLIA SASANQUA.

THOUGH the flowers of this species are too fugitive to warrant it ever attaining anything like the popularity of *C. japonica*, it is still well worth a

the colour in the different varieties ranging from white to bright red, and the size from 2 to 4 inches across. Both the type and its varieties grow freely, and soon make good sized, well shaped bushes if treated in a similar manner to *C. japonica*. Most of the varieties are under

FIG. 17.—CAMELLIA SASANQUA.

place in the greenhouse, as its single or semi-double flowers are exceedingly pretty and produced in profusion when the plants are well grown. It is a Japanese plant of dwarf bushy habit. The leaves are oblong, 2 to 3 inches long and three-quarters of an inch wide. The flowers (fig. 17) are very variable, some plants having single, some semi-double flowers,

Japanese names—names which in Japan are no doubt highly esteemed, but in England strike terror into the gardener's heart, as, for instance, *C. S.* var. *Fukuzutsumi* and *Azumanishiki*. The type is figured in "Thunb. Fl. Japan," p. 273, t. 30, and a variety in the "Botanical Magazine," t. 2080.—W. D.

SEASONABLE NOTES.

In the "Rosarians' Year Book" Dr. Shackleton strongly advocates the use of standard Roses for suburban gardens, as tending to lift the Rose growth into a clearer atmosphere. There may be some force in this remark, but I am inclined to think the main benefit is derived from the plant being less liable to rain splashes and dirt. A Rose upon a standard or half-standard stem looks larger, and is decidedly showier than the same sized plant would appear when grown as a bush. For many years we have cultivated the weaker-growing Teas and Noisettes in this form, and also those with a tendency to drooping blossoms, such as *Souvenir d'un Ami*, *alba rosea*, and *aman Cochet*.

The short Briar stem, and those reaching to some 2½ feet, suit a most any Rose; but when taller stems are used it is well to have vigorous growers, and those producing long rods, that will be covered with blossoms throughout their length, and droop over in more or less weeping form. When grown in the centre of Rose beds, or singly upon the lawn, such standards are seen to advantage; but we must have strong, or at least very free growers. And if the greater longevity of dwarfs has lessened the proportion of standards that were formerly grown, few forms are showier when a judicious selection of varieties has been made; and much more depends upon this in the case of standards than with dwarfs.

We have a large death roll among standards because we are treating the stock itself in so unnatural a manner by constantly cutting away the suckers all Briars almost invariably throw as soon as established. With dwarfs we bud close upon the crown of the root, and few suckers result. In standards we leave the whole of the root free, and a large proportion of the stem. It is the nature of Briars to make vigorous and rather coarse roots, and to throw out suckers from time to time. If we curtail this we must provide a Rose of sufficient vigour to keep the roots active, and be able to draw the sap up the Briar stem.

If we work a weak-growing variety as a dwarf upon such vigorous stocks as the *De la Grifferaie*, we soon find it overpowered and rapidly deteriorating. No doubt this is caused by the great contrast between the constitution of Rose and stock. On the other hand, a naturally vigorous grower will give a very different result, as the stock and Rose are more at union in their requirements. Briars in a state of nature produce long, coarse roots, and often develop suckers throughout their whole length, and this in spite of the most careful trimming of roots. To avoid this it is a good plan to lift the plants every four or five years in order to cut such away more thoroughly. The lifting when done in season is decidedly beneficial rather than harmful, and we get more fibrous roots. We plant Briar stocks early in the autumn, and should do the same with standard Roses, for after all it is the Briar we are considering when transplanting.

Hybrid Perpetuals to be forced in pots should be pruned now and cut back harder than many practise. We only grow these under glass because of their deep and glowing colours. Other shades can be much better obtained from the Teas and a few Hybrid Teas. Of all H.P. Roses *Général Jacqueminot* is far away from the rest as a forcer. It is a freer bloomer than others, comes a good colour, has pointed buds, opens well, and is deliciously scented. All of the H.P.'s should be brought on very steadily until they show new growths of some inch or so in length, after which a gentle rise may be given until the flower buds are discernible, when they may be forced at will. But if we hurry and excite the sap in the wood too much before the roots are active the result is 2 inches or so of growth, and then a sudden check, which is generally fatal to many flowers.

Because the weather has been so mild, and a few Roses are pushing into growth in sheltered places, I note that several have begun pruning. But none of these was a Rose grower. It was invariably that most useful man who can do and understands everything pertaining to the garden. We all know him. By no means prune until the end of next month, let the weather be what it may. How many bushels of Roses are cut away each year late in the autumn when our friend the jobbing gardener is tidying up the villa garden for the winter months. Long growths of our showiest Roses are removed as useless because they did not flower during the past summer, and

are waving about in the way. They are really the most valuable wood of all, and will produce by far the best and greatest number of blossoms in the following year. It is such an easy matter to secure them until pruning time arrives, when, as a rule, with that class of Rose all we have to do is to thin out old wood to make room for the very shoots I have recently seen cut away so ruthlessly.

Turning once more to Roses under glass, I would say a few words about those in unheated houses. These are pushing into growth, and as the sun gains power will progress rapidly, unless we get a spell of cold weather; even then they are apt to be premature in growth, only to be caught by cold weather when some 3 inches or so long. Give as much ventilation as possible, and keep them backward until the early part of February. When they do start, the heat from sun and shelter from glass will bring them along apace—too fast, in fact, unless one is very careful to regulate by ventilation. This is the difficulty with Roses in unheated houses—one cannot be sure of a fairly uniform temperature. But much can be done in keeping the plants back until such time as the protection from glass will be sufficient to save from late frosts. Often have I flattered myself that the plants were carrying healthy and promising young growths, that were so far advanced as to be almost certain of a satisfactory crop; but a few dull days, and the inevitable damping when one is not able to use a little fire heat to counteract it, have been fatal. It is the same from cold, if we hurry our plants too much at first.—PRACTICE.

EARLY PEAS.

DRY, warm sheltered borders are to be found in some gardens very suitable for the production of early vegetables. If, in addition, the soil is rich, deep and fertile, or can be thoroughly well cultivated by double digging or trenching as well as liberal manuring, it will be in fine condition for sowing an early crop of Peas. A few rows of the round seeded first early kinds, such as *Sutton's Bountiful*, *William I.*, and *Dickson's First and Best*, may be sown at once. There are also early wrinkled seeded varieties, some of the best being *William Hurst*, *Chelsea Gem*, and *English Wonder*. All these are reliable dwarf varieties, which under favourable conditions give good returns by producing splendid crops of tender Peas.

Narrow sloping borders, well protected on every hand, but fully open to the sun, ought, if possible, to be chosen for these early crops. It is the cold cutting winds of spring which are the greatest enemies to the young Pea growth, hence the need of adequate shelter, which may be further enhanced by early furnishing the Peas with sticks. Early Peas may be sown somewhat thicker than varieties sown subsequently. Place the seeds in drills, 3 or 4 inches wide and 2 inches deep, drawn with a hoe. Cover the seed with fine soil, and then fill up the drills with the soil on each side. Three feet distance between the rows is a suitable distance for early crops, as all the varieties are of dwarf growth.

In addition to sowing outdoors, it is quite feasible to advance an early crop by sowing in boxes, pots, or on strips of turf under glass, but not under the influence of heat. Strips of turf may be laid grass side downwards in boxes, the ends or bottoms of which are movable. Wooden or zinc spouting answers well. Scoop out a space in the soil to receive the seed, not sowing too thickly, and cover with fine soil. Place in a frame or cool house where germination will be steady, consequently the young plants will advance sturdily. Plenty of air must be afforded them, and a position near the glass. If sown in pots, employ those 3½ or 4 inches in diameter, and stand them on a moist base. The turf used or the soil being thoroughly moist at the time of sowing, only a slight sprinkling of water will be necessary after the seed is covered.

The most important matter is to prevent them growing too quickly, whereby the plants become drawn. This can only be effected by a constant circulation of air about them, and giving them exposure to the outer atmosphere on favourable opportunities, hence the value and convenience of frames from which the lights can be drawn off. Previous to planting them out in the open, fully expose for some time, protecting from sudden frosts and rough winds.

Plant in shallow trenches, which afford a little protection from the winds, and furnish them with short branching stakes as support, giving the rows further shelter by affixing branches of evergreens on the windy side. The latter can be removed when the rows are fully established, and the weather is favourable for growth.

If dry warm weather sets in at the time of flowering, muleh down each side of the rows with light manure, and afford them water if necessary. When the pods begin to swell, diluted liquid manure will help the crop considerably.—E. D. S.

RAISING PEAS UNDER GLASS.

In perusing the columns of your valuable paper I have not seen a really practical plan given whereby those who wish to have early Peas with as little inconvenience as possible, and are obliged to sow indoors,

can do so. We read of first early Peas being sown in pots or on turves, and although I have not seen either method practised, I can vouch that the following plan gives satisfaction.

During the past ten years we have grown first early Peas in boxes 4 feet long, consisting of two 7-inch boards placed slantwise, having detachable grooved ends, thereby making the whole more substantial. In filling the boxes the soil is used fairly dry, and after sowing is firmed down well, a square-edged board being drawn along the surface of the box to give it a workman-like finish. The boxes are then placed in a cold vinery which is not started till the 1st of March. When the Peas are 3 or 4 inches above the soil the boxes are removed to a cold frame, ventilating, and drawing off the sashes as much as possible to keep the plants sturdy. The boxes are eventually set out in line in a sheltered position in the open.

In planting, a drill is made with the draw-hoe similar to the shape of the boxes, and while one man holds the box, another knocks off one of the detachable ends, and with a mason's trowel, or a long-bladed knife, relieves the roots, which will have got imbedded to the sides of the box, then shaking this, the whole mass slides into the drill; a little earth is drawn up to the plants and sticks inserted along the rows.

When the plants are well prepared and the work properly finished a novice would conclude that they had been sown in the position. Having proved this to be an easy, simple, and satisfactory plan of securing first early Peas, of which we grow Gradus and Exonian, I can recommend it to anyone wishing to give it a trial.—IOTA, *co. Antrim.*

[We readily publish the experience of our correspondents. The plan, however, of raising Peas in trough-shaped boxes is not quite new. We very well remember it being practised forty-five years ago, but in shorter and generally smaller boxes than those described and handy for one man to manage. Four years ago we published a method of raising early Peas as described by a correspondent, "W. S. E." As many persons tried the plan, some finding it good, others the reverse, we reproduce it (figs. 18, 19, 20), and point out that those who failed had done the joinery work too

FIG. 19.

FIG. 20.

well. They did not make sufficient allowance for the swelling of the wood, and the bottom, instead of being easily withdrawn, was something like a fixture. With abundance of "play" allowed when the boxes are made, there is no difficulty whatever when the time arrives for transplanting.

"I enclose a sketch that I think will almost explain itself, and anyone thinking of making boxes would find much trouble saved in the operation of planting if they had them constructed as advised. It will be seen that the bottom is loose, and is simply slid in and rested on the two strips of iron or wood. To plant, a trench is made, a box is placed in the end, the bottom drawn out, and the box is lifted straight up. The bottom being wider than the top allows the mass of soil with the Peas to drop out and remain intact in the trench. All that then remains to be done is to draw the soil up to them on both sides; this is repeated to the end of the trench."

"A handy and useful size would be 2 feet long, 3 inches wide at the top, 4 inches at the bottom, and the same in depth, inside measure. The ends should be made of wood 1 inch or $\frac{3}{4}$ inch thick, and cut to the size named. The sides may be made of $\frac{1}{2}$ inch wood, and for the bottom $\frac{1}{2}$ or $\frac{3}{4}$ will be strong enough, and should answer without any additional support. The best support for the bottom would be irons $\frac{3}{4}$ inch wide, $\frac{1}{4}$ inch thick, and bent to shape with two or three holes for nails or screws, as shown in fig. 18. They would then go through the sides and into the thick wood of the ends. The bottom should be 2 or 3 inches longer than the sides to enable anyone to draw it out from either end, and it must be made to slip in very easily, as in watering the Peas the wood will swell and make it difficult to draw out. A handy man would soon make a number out of old packing cases, which are usually to be had on a gentleman's place, and if taken care of they would last several seasons.

"Fig. 19 shows a portion of the box at one end. A A are the sides of the box; B, the end; C, bottom partly drawn out; D, narrow strip of wood or iron, the same width as the thickness of wood in the end of the box, one of these at each end supports the bottom; E, shows how extra support may be given to the bottom, if required, by two nails and a piece of string. Fig. 20 shows the box endways."

THE N.C.S. AND THE CHAIRMAN'S RESIGNATION.

ON asking a member of the N.C.S. for the cause, so far as he knew it, of the announced resignation of Mr. T. W. Sanders, for the purpose of answering a question on the subject, we received the following reply:—

"Mr. Sanders resigned last year, but was persuaded to remain. This time I daresay he means it. His reasons were purely diplomatic—pressure of business, other engagements, and so forth. I hear his is not the only withdrawal. We are a merry family, we are! we are! we are! Perhaps we shall have an infusion of new blood some day."

The information, it will be conceded, is a trifle enigmatical, but the jaunty air of the member suggests that he intends to be happy whatever changes may occur. Perhaps he knows very little about them.

We have received another budget of complaints and grievances against the N.C.S., but they cannot be attended to this week.

MR. GODFREY AND THE N.C.S.

I AM perfectly willing to concede to Mr. Godfrey or to anyone else the fullest right to insert what they may prefer in their plant or seed catalogues; but the moment they send these lists out to the public the contents become so far public property that if referring to public matters they are amenable to public criticism. Any ordinary seed or plant list that is confined to its legitimate purpose, and does not include contentious matter of public interest, is quite outside the pale of criticism. Out of the numerous Chrysanthemum lists sent me from leading growers some have contentious matter in them, others have none. I prefer the latter.

My special reason for drawing attention to and deprecating these objectionable introductions into lists, was found in remarks made by two or three gardeners, who, utterly unconcerned as to the N.C.S., its sins or its virtues, complained of their unseemliness. I think it is probable, as a result of these strictures, that similar offences against good taste will not be extended.

As to the relative quarrels between the various traders and the N.C.S. I have no concern, but so long as the National Chrysanthemum Society holds that these traders cannot do without it (and traders practically admit it is so, because they continue to exhibit at the Society's shows) the latter have no right to complain if they do find themselves apparently scurvily treated. If, on the other hand, they are all fairly treated, why so much grumbling? We hear more of it in connection with the Chrysanthemum than with any other plant, flower, or fruit exhibited.

The Chrysanthemum is admittedly a most beautiful flower, and yet somehow it is productive of more quarrelling, grumbling, and grasping than is any other. We see nothing of this in the Rose, Dahlia, Carnation, and other plants, or in exhibitions generally. Is it because exhibiting Chrysanthemums is made, by both exhibitors and traders, primarily a money getting or making object? Anyone who can assist to purify the Chrysanthemum world of this unpleasant element certainly is doing useful work.

Let us see more of pure love for all that is beautiful in Chrysanthemums made more prominent at shows, and more of true love for them as home decorative flowers. No doubt the present system of demanding huge blooms at shows is largely responsible for so much of the selfish element in exhibiting. The more flowers are shown for the production of purely decorative effects, the less will the selfish element be evidenced.—A. D.

AWARDING PRIZES AT THE N.C.S. SHOWS.

IN the Editorial footnote, page 68, I note the paragraph, "We have received more complaints relative to the awarding of prizes at the N.C.S. Shows, than from exhibitors at all other shows in the kingdom." The italics are mine. I rather think a mistake has been made in the word "prizes," and that awards were probably meant to non-competitive exhibits. Considering the magnitude of the shows of the N.C.S., I consider grumbings at the awarding of the competitive prizes have during the last few years been exceptionally few; at least, they have not come within my knowledge, though this is perhaps not proof of the absence of such complaints.—A N.C.S. JUDGE.

[It certainly is not; nor does it follow that all complaints are well founded. There are prizes in the form of medals and other articles at shows, as well as of money, and judges "award" them, whatever they may be. The letters which we have received from time to time, and of which only portions of some of them have been published, have had reference mainly to other than the classes in which money

prizes were awarded, and our correspondent seems to carefully exclude them from the scope of his remarks. Had he expressed approval of all the exhibits and awards granted for them he would have weakened the force of the complaints, the existence of which he tacitly acknowledges. He knows better than we do whether there is justification or not for the "grumblings," as he is familiar with the precise terms of the schedules under which all the awards have been made, and we are not. Our correspondent seizes on what he conceives a questionable word, but evades the substance of the complaints, with which it is impossible he can be unfamiliar. We find no fault with him, as every man has a right to adopt any fair tactics for attaining the object he has in view. In this case he touches the fringe of the subject of exhibiting and "awards" tenderly; yet he is not by nature a particularly nervous man, though generally discreet.]

INCURVED VARIETIES.

IN my opinion the members of the Classification Committee of the N.C.S. are much to blame for the low standard of incurved blooms that are met with at the autumn shows at the present time. The inclusion of so many varieties that are of such doubtful quality as the list given on page 66 is a strong proof of what I say. Take, for example, one variety in each column—Madame Edmond Roger and The Egyptian—a long stretch of imagination would be required by any person to honestly say that either sort is even a fair representation of a typical Chinese blossom.

If the Committee fixes such a low standard what will happen to the incurved section in the near future? By maintaining a high standard of quality as a minimum we may expect improvement in the general quality, but when such sorts as I have named are permissible in a collection, how can we reasonably look for any improvement?

From the five dozen sorts named it will be safe to say that not more than two dozen at the outside (more likely one) will live long enough to become favourites. If this surmise prove to be correct the Committee will hardly feel flattered with the choice. Some of the varieties in the list are extremely "rough," owing, no doubt, to the Japanese blood infused into them as seedlings with a view to obtain enhanced colour. If the members of this Committee (I cannot believe they were unanimous) wish to see the sorts cultivated they have given the hall mark to, they should relegate them to the Japanese section, where they would quickly find their level—namely, the rubbish heap.—SADOC.

[It is pitiable to see so many mongrels passed into the incurved section.]

CHRYSANTHEMUM PROBLEMS.

(Concluded from page 14.)

IN attempting to divert Nature from her own manner of doing her own work to suit our requirements, we may instance an early blooming variety of Chrysanthemum showing a plump decided flower bud which, unfortunately, may be ten days too early. We start the plant on another instalment of growth, which has to be made during the naturally decreasing favourable conditions of growth attendant on our autumn climate; this is further aggravated by a spell of dull and cold weather. We have upset the balance of Nature; but there is not sufficient time for her to readjust it. For the new growth she is bound to use up wholly or partially the reserve store which was meant for the bloom alone. At the best it is divided between growth and the belated bloom, resulting in a compromise where neither bloom nor wood can be satisfactory. This phase of upsetting the balance between growth and blooming is well illustrated by stopping those varieties in March, April, and May, which otherwise cannot be obtained with any degree of success, proving that stopping of itself is in no way detrimental if sufficient time be allowed for the plant to readjust the balance.

Viewed by the light of the foregoing comments, although the later varieties require a longer period of sunshine to ripen that instalment of growth which is made from the time of stopping to the flower bud stage; but once the knowledge of the time required is gauged for each variety within reasonable limits success is more certainly achieved, because the complications are fewer.

In deciduous flowering and fruit trees, their yearly accretions of firm wood serve as a more permanent storehouse of the products of elaboration, and under good cultivation with the requisite water supply they can scarcely become over-ripe. But although the process leading up to the storage of those products is the same generally, in the Chrysanthemum the demand on them is made during the same season, because it blooms on the current year's growth, which naturally is not of a permanent character, being replaced by new sucker growth directly from the old stools. The plant can therefore only be regarded as a herbaceous one, a little more highly organised than the general run of that class of plants on account of its somewhat woody character. Viewed in this light we obtain the cue to one phase of over-ripening, which is more prevalent than ordinary observation leads us to understand. In herbaceous plants as the autumn approaches with maturing

and matured top growth we find a corresponding decrease of root action, both top and root practically going to rest. As a parallel to this, when we select an early blooming variety of Chrysanthemum, because under natural conditions it is capable of producing a fine bloom, we propagate it with the later varieties, which require a longer season to ripen. By high cultivation of the early variety we prolong its natural season of growth beyond its time, forcing from it several extra instalments, so that the bloom is carried forward to the exhibition season so long as the plant does not become too "ripe."

As bearing on this argument, another interesting phase of culture is where experience points to proving that some varieties produce better quality blooms on second crown buds, the prevailing opinion being that the bloom resultant from this bud is finer in quality, broader in the floret, and carries greater depth. Whilst allowing for the typical differences between crowns, second crowns, and terminals, we have also to concede that less wide variations occur in quality of second crown blooms as are to be found in other types. But where the best results accrue is when the combination of favourable circumstances takes place in regard to the proper degree of ripeness as discussed when referring to the early section—viz., not too ripe as to cripple root action, but in that condition when functional leaf activity is vigorous, and fully reciprocated by vigorous root action onwards till the bloom be fully developed. In reference to the question of the general superiority of the second crown bud on its own merits as such, we must not lose sight of the influence of climate on the development of the bloom. As a rule with those varieties grown on the second crown, if left to their natural course, the first crown would be too early and the second too late, so the chief object in stopping them is to secure the best-timed buds in the autumn, when climatic conditions are most favourable to alter development of bloom.

Having secured growth at the same time in its proper degree of ripeness typical September weather is no doubt the most favourable for bud development, which is represented by a moderate degree of atmospheric moisture, with plenty of sunshine by day, and cool enough at night to bring the atmosphere to saturation point, as exemplified by heavy dews in the morning. Unless these conditions obtain, even a difference of one week in obtaining the buds has an important effect on the quality of the bloom.

In the English Lake district the climate is considerably moister, even during summer, than other parts of the country, whilst the light is remarkably fine, and the temperature lower and more equable all through the summer. Typical September weather, as above described, is therefore a more certain quantity than elsewhere, yet I can vouch for the Japanese Chrysanthemums there grown from crown buds being equal to the best in size, quality, and colour grown elsewhere, whether on the first or second crown. It would obviously be rash to insist upon the general superiority of the second crown bud to the first, when all the conditions to development are as favourable to the latter as to the former.—T. G. W.

SOIL ANALYSES.

I CANNOT quite say of "H. H. R." (page 48) what someone has said of Mr. D. Thomson—namely, that he "always appears to say a great deal in a small space" (page 46). I said nothing whatever about the discussion on a paper read at the Drill Hall, for the sufficient reason that I knew nothing; but I did say on page 23 that your Forest Hill correspondent was an adept in taking ideas from books that he thinks favour his views, and ignoring precise statements which are condemnatory of his notions on soil analysis. This is absolutely the case; and notwithstanding his being, as he indicates, a life-long "learner," he only seems desirous of learning that which is in harmony with his own preconceived notions.

On this soil analysis fad—for fad it is as measured by his requirements—this "no chemist" places himself in direct conflict with a recognised scientific authority, for such Mr. Cousins must be to occupy his responsible position at Wye. Of what possible use could it be to "H. H. R." or anyone if I were to state the amount of lime discovered by analyses in samples of soil with which he has nothing whatever to do, and the particulars of which could afford him no guidance whatever in his dealings with different soils?

I could furnish details of a dozen analyses that I can truthfully say have been of no use to me, and I should be sorry to assume that any editor would publish them. I do not despise the aid of science by a very long way, and have been glad to benefit by it in the purchase of manures and in other ways, but the clamour for soil analyses, of which no two samples are alike out of many over the same area, and which, moreover, vary from different analysts, has no response from intelligent practical men. In my experience, for ordinary purposes of cultivation, digging a hole here, another there, and a third not far off, and so on up to a dozen, boxing the precious stuff, and sending it to some laboratory for the purpose of ascertaining what it will grow, is the merest fiddle-faddle, and a time-wasting process.

What any particular soil will grow depends on the cultivator who has it to handle, and who sees the natural vegetation, very much more than on any mystery man locked up in a room in some "foreign land" or elsewhere. As a cultivator I know this to be true, because I happen to have been much more bothered than helped by a gentleman with science on the brain, and who was really more than a "no chemist."

If a gardener who digs down, into the soil and examines it carefully, notes the trees, vegetables, flowers and weeds growing on it, and then cannot make the best of it, there are plenty of others who can. I fear "H. H. R." has no very good opinion of British gardeners, since all he has written goes to show how far they are behind, because they do not analyse the soil in the way he approves. Yet I venture to say that ninety-nine out of a hundred of all the best examples of cultivation he has seen have been produced in the absence of what he fancies to be necessary.

How any person who is "no chemist" can cite in support of his views an author who is a chemist, and this very author does not support, but confounds him in the extracts on page 24, and then passes these extracts—the proofs against himself—without an acknowledgment of their existence, is beyond my comprehension. If "H. H. R." is right Mr. Cousins is wrong on this question of soil analyses. That is the point at which we arrive, while the confessor of ignorance in chemistry complacently assumes that he, himself, is right. On one point he does not insist, namely, that an analysis for lime alone would be cheap at £6, but quietly drops £5 10s. This shows progress, even if that of the man in the boat—backwards.

One word more as a test of the practice of "H. H. R." Has he worked all the long years he implies in his own cultures on the basis of soil analysis? Has he sent what he demands from others—the results of analyses of his own soil to the editor? Of course he may have done so, and the figures have not been published. But has he? And with what results? Let me say that years ago I sent records of my experiences, so I am not asking of others what I have not done myself as—AN ENGLISH GARDENER.

TOMATO CULTURE.

(Continued from page 62.)

Sowing Seed.—Plants from seeds are superior to those from cuttings in produce. If the seed be sown during the first fortnight of January, and early varieties are selected, such as Early Dwarf Red and Early Ruby, with Comet and Mayflower, the plants being grown strongly and without check, ripe fruit may be had from them in April or early in May. Sow the seeds very thinly in well drained pots, pans, or shallow boxes, using light sandy soil. The soil should be rather firm to induce the seedlings to grow sturdily and push roots at the "neck." Cover lightly with fine soil. The practice commonly pursued is to plunge in bottom heat, cover with glass until the seeds have germinated, then transfer the pots to a shelf near the glass. If the heat is not great and the removal be gradual, no check will be given the seedlings.

There are, however, risks in it, and the better plan is to either have the plunging bed so near the glass that the seedlings cannot possibly "draw," or dispense with bottom heat altogether. The latter system means hard plants, blue-green in colour, and short stems; while the former implies yellowish foliage, a considerable up-growth, and a somewhat spindling stem. This can be obviated by keeping the top heat relatively low and letting every plant have all the light and air possible by judicious thinning of the seedlings, always withdrawing the leggy and weak and retaining the sturdy and most promising. In a Cucumber house with a night temperature of 60° to 65° day, 70° to 75° up to 90° with sun, Tomatoes can be raised very well on shelves fixed 1 foot from the glass. The bottom heat tends to weaken the plants and make them more susceptible to "sleepy disease" and eelworm. The Tomato appreciates a little air, a temperature of 55° to 60° at night, 65° by day, and 70° to 75° with gleams of sun.

When well into rough leaf, not more than a pair other than the seed leaves, place the plants in 3-inch pots, lightly drained, using soil warmed to the temperature of the house. If the plants are sturdy and are carefully potted they will hardly flinch. It is the lankiness (fig. 21, A) and the tenderness (a) that causes the seedlings to hang their heads after potting, while many such may have the stems crushed (b), which then decay and the plants are spoiled. Care must be taken to avoid that, placing a little of the roughest soil over the crocks, then a little finer, and enough to raise the seedling with its stem buried to the seed leaves in the soil, a quarter of an inch from the top of the pot. That space will be sufficient for holding water for the plant.

Observe what a difference there is between a drawn plant and a stout short-stemmed one (B c). For the first (C) the 3-inch pot is hardly deep enough, its radicle has to be bent on the rough compost,

and reliance placed on the emission of roots from a part of the plant containing little stored matter. It cannot be pressed; the soil so treated would crush its life out, therefore very light potting and a gentle tap down is all the weakling will bear. The stout-stemmed seedling (D) takes a lot of soil below its radicle or tap-root, and it has so many side roots as to practically come out of the seed pot, or pan or box, with a ball. It need not be sunk deeply to get it, with the seed leaves, just clear of the soil at the proper level, hence no weak stem in the soil to fall prey to vegetable or animal parasites, while it takes to the compost at once.

To get good plants it is better to prick off the seedlings when coming into rough leaf (E), like Cucumbers and Melons, and either pot them in "thumbs" or place round the sides of pots not less than an inch apart. I found that shifting checked the tendency to weakness, and the extra transplantation had a material effect in the matter

FIG. 21.—RAISING TOMATO PLANTS.

References.—A, thick sowing; a, drawn, spoiled seedling; b, crushed seedling. B, thin sowing; c, stout seedling. C, section of pot showing lanky plant potted off. D, section of pot containing sturdy seedling potted off. E, seedlings pricked around side of pot while in seed leaf. F, single plant shifted into 5-inch pot. G, pair of plants transferred to 6-inch pot.

of early fruitfulness. The plants cannot be too stiff, and the seedlings certainly root better at the sides than in the middle of pots, no matter what size.

Some growers pot the seedlings two in 5 or 6-inch pots, called the pair system, strong plants being selected. It may also be called the one-shift method, single plants being given 4-inch pots, out of which they go respectively into 10 or 12-inch pots for fruiting, or into either boxes or narrow beds. The newly potted plants should be kept somewhat close, and shaded from bright sunshine for a few days. The "miffy" plants will profit by a little bottom heat, and even extra warmth for a time; but they are not worth either; far better throw them away, and be a month later with sturdy healthy plants.

For these reasons I lay stress on the "hard as nails" plant, potted or pricked off early, and then transferred, before root-bound or grown too large, into 5-inch pots for singles (F), and 6-inch pots for pairs (G). In these keep them until the first blooms appear or show, then transfer to the fruiting quarters. If they are grown "hard," they will do this before they become root-bound or much weakened in growth, but by no means allow them to become stunted, but repot as required, whether from the small pots into large, or from these into the fruiting quarters. Some growers do not wait for the development of the first bloom, but shift

the plants and get them well established in the fruiting quarters before the first blooms are set.

That is the crux of raising Tomato plants from seed. Never over-water or allow the plants to become dry at the roots as to cause flagging. Room is another great point, for the plants will grow up if they cannot spread out laterally; therefore get stamina into the seedlings from the moment they appear above ground, and remember they want as much air and as much light to be able to bear fruit as the Potato does to produce mealy tubers.—G. ABBEY.

(To be continued.)

SOWING BROAD BEANS.

WHERE Broad Beans are in demand advantage should be taken of the earliest opportunity to make a sowing of Early Longpod or other variety of this class, as they are the hardiest and earliest in coming into bearing. Windsor Beans are not so early, but superior in quality, and may be sown as a main crop variety at the end of February or early in March.

Broad Beans require good, rich, substantial soil, but the situation for early sowings may be warm and sheltered. Where the soil is light in character deep culture and liberal manuring are highly appreciated by this crop, because the plants make strong growth, and are consequently gross feeding. Sow the Beans in double rows and 2 inches deep, the rows being 2 feet apart for the early, and 3 feet for the main crop. The two lines of the double row may be 8 or 9 inches apart.

After the seed commences to germinate and come through the soil the surface may be frequently hoed over in dry weather. This will promote the growth better than any other attention, inasmuch as it admits air and warmth into the soil while preventing the escape of moisture and keeping the ground clear of weeds. This will keep them growing well and bring them into flower as soon as desirable. When the flowers have set nip out the points of shoots, as it almost invariably happens that black fly attacks the plants if this is not done. Even if there should not be any fly the practice of stopping the tops is desirable, as it helps the pods to swell.—S.

NOTES ON FIGS.

AT wide intervals during the past year I have sent to the *Journal of Horticulture* brief seasonable notes on Fig culture under glass. This I propose doing again, as though houses of Figs are not found in every establishment their cultivation is sufficiently extensive to make the observations of value. Obviously general details cannot be afforded unless a series of articles be given, and those might not have the same value as concentrated hints.

EARLIEST TREES IN POTS.

The trees being now in full growth the points of the shoots must be pinched out when they have made about five leaves. A temperature of 55° to 60° at night, 65° by day, advancing to 70° with sun heat, closing early, and allowing an advance to 80° or 85, is suitable for the present. When the weather is dull afford a slight increase of heat in the early part of the day, so as to admit of a little ventilation, if only for an hour or two, to effect a change of atmosphere and induce sturdy growths. The bottom heat should be kept steady at 70° to 75°, introducing fresh sweetened leaves and litter as necessary. Syringe frequently to keep the trees free from red spider, and always sufficiently early to allow the foliage to become dry before night.

EARLY TREES IN BORDERS.

The trees started at the new year have commenced growth and the temperature slightly raised. A warmth of 55° will be suitable at night and 60° to 65° by day, with a rise to 70° or 75° from sun heat, and a free circulation of air, as a drawn and weakly growth cannot afterwards be rectified, and must be avoided by free ventilation on all favourable occasions, striving to secure a sturdy short-jointed wood from the commencement. Syringe the trees twice a day on fine days, but when dull morning syringing will be sufficient. The border will require copious supplies of tepid liquid manure, or watering through a mulch of manure in a lumpy state, so as to allow the roots to have the benefit of the air. Avoid, however, making the trees exuberant, as that is fatal to fruitfulness. In order to secure the free and certain swelling of the first crop of fruit keep the growths somewhat closely pinched, say at the fifth leaf, and rub off side growths not required to occupy vacant space or to form the so-called spurs.

SECOND EARLY BORDER TREES.

The house to afford fruit at the end of June or early in July may now be started. The trees will afford a second crop of fruit in September which will be very acceptable. If the trees have not had the old bare growths cut out, so as to leave the successional wood with its terminals for furnishing the first crop, and been dressed with an insecticide, these matters must have immediate attention. The border should be brought into a thoroughly moist state by repeated watering if necessary with tepid water, or where the borders are small and the trees large liquid manure may be supplied. Syringe the trees twice a day in bright weather, occasionally only when dull, but damp the floors and borders so as to secure a genial atmosphere. A temperature of 50° at night, and 55° by day artificially, is sufficient to commence with, advancing to 65° from sun heat, with a free circulation of air.—GROWER.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—JANUARY 31ST, 1899.

THE display of flowers in the Drill Hall on Tuesday was very much more interesting than might have been expected. Orchids and Primulas were handsome, as were the Apples from Messrs. T. Rivers & Son. Each Committee had exhibits to attend to, but the Orchid was, perhaps, the busiest section.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Messrs. A. F. Barron, W. Poupart, A. Dean, J. W. Bates, F. Q. Lane, G. Reynolds, J. Willard, and the Rev. W. Wilks.

Messrs. T. Rivers & Son, Sawbridgeworth, staged an excellent exhibit of Apples and Oranges. The former were very fine indeed, and comprised splendid examples of Gloria Mundi, Gascoyne's Scarlet, Buckingham, King of Tompkins County, Belle Dubois Melon, Lord Derby, Bailey's Sweet, Wadhurst Pippin, Lewis' Incomparable, Emperor Alexander, and Bijou. The Oranges comprised well grown varieties of St. Michael's.

Mr. W. Roupell, Roupell Park, exhibited a basket of Apples, consisting of Newton Wonder, Smart's Prince Arthur, and Annie Elizabeth; the specimens were well preserved and presented an attractive appearance. Mr. Francis Calvers, Ludlow, exhibited a seedling Apple named "Collin Calvers," but the fruits were evidently past their best. The same exhibitor also staged a dish of Pear St. Julien.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. O. Thomas, H. B. May, R. Dean, W. Howe, C. Jeffries, J. Fraser (Kew), E. T. Cook, J. Hudson, J. Jennings, T. Peed, R. B. Lowe, C. E. Pearson, W. Bain, J. D. Pawle, R. W. Ker, J. Walker, C. E. Shea, J. W. Barr, H. J. Jones, H. J. Cutbush, C. Blick, and G. Paul.

Messrs. J. Hill & Son, Lower Edmonton, exhibited a choice collection of Ferns, comprising good specimens of *Gymnogramma calomelanos*, *Asplenium Colensoi*, *Davallia hirta cristata*, *Nephrolepis davallioides furcans*, and many others (silver Flora medal). Messrs. H. Cannell and Sons, Swanley, contributed a fine collection of Primulas. The plants were grown in 6-inch pots, with very healthy foliage and an abundance of bloom trusses. Cannell's Pink, White Perfection, Duchess of Fife, Beacon, Snowdrift, Mrs. R. W. Cannell, The Sirdar, Cannell's White, Red Rover, and Kentish Queen were the most noteworthy of the single forms, while the double forms were well represented by Princess of Wales, King of Purples, Marchioness of Exeter, Earl Beaconsfield and Annie Hillier; the plants of the latter were all beautifully flowered (silver Flora medal).

Messrs. Jas. Veitch & Sons, Chelsea, staged a box of hybrid Rhododendrons, comprising many beautiful forms. The trusses of Conqueror, Princess Beatrice, Ceres, Purity, Minerva, Brilliant, and the double form, balsaminæflorum album, were very attractive. Mr. R. Owen, Maidenhead, also contributed a capital display of Primulas. The plants were well grown and the flowers varied in colour, from white to pink, heliotrope, blue, red, crimson and purple, with many intermediate shades. The strain is undoubtedly a good one (bronze Flora medal).

Messrs. J. Laing & Sons, Forest Hill, staged a tasteful group of foliage and flowering plants. The Crotons were well coloured, while the Palms, Dracenas, and Ferns were enlightened with splendid plants of *Begonia Gloire de Lorraine*, *Cypripediums*, and Oranges in pots. Mr. F. Miller, 110, Fulham Road, South Kensington, exhibited an extensive display of floral decorations. The spring flowers employed consisted of *Acacia dealbata*, Snowdrops, Lily of the Valley, Tulips, Narcissi, *Spiræa*, white Lilac, common Primroses, and Freesias. The display did much to enhance the attractions of the hall (silver Banksian medal). Messrs. F. Sander & Co., St. Albans, exhibited excellent plants of *Acalypha hispida* (Sanderi), again demonstrating its value for winter-flowering. Good specimens of *Dracena Godseffiana* and *Sanderiana* were also staged, with plants of *Acalypha Godseffiana*, a variegated plant of much beauty.

Messrs. Collins Bros., Hampton-on-Thames, exhibited a number of Narcissi, comprising a good display of *N. telamonius plenus*, *N. spurius*, *N. poeticus ornatus*, and *N. princeps*. The blooms were displayed in vases, also in boxes, as packed for market. The bulbs were all grown at Hampton, and have certainly given good results (silver Banksian medal). Messrs. Barr & Sons, Covent Garden, staged a very pretty display of spring-flowering plants, comprising pots of *Narcissus minimus*, *Chionodoxa sardensis*, *Iris reticulata* var. *Histria*, and *Cyclamen ibericum rubrum*, *C. i. roseum*, *C. Atkinsi*, and *Veltheimia viridiflora*. Sir Trevor Lawrence, Bart., Dorking, exhibited some fine clumps of *Helleborus* Stephen Olbrich, and Frau Sophie Fröbel, both forms of a purplish rose colour; also a seedling of the same colour, heavily spotted with purple. From this source came a beautiful variety of *Lapageria rosea*, Knoll variety, a remarkably fine form, the flowers and foliage being quite distinct from the Nash Court form.

Messrs. T. Cripps & Son, Tunbridge Wells Nurseries, exhibited a group of *Rogeria cordata*. The plants ranged between 4 or 5 feet in height, and produced the flowers in numerous terminal trusses of pinkish colour. The foliage was bright green. Mr. H. Guyett, gardener to Mrs. Gabriel, Elmstead, Streatham, exhibited bunches of a *Rhododendron* gathered from the open air.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, H. M. Pollett, H. Ballantine, H. Little, J. Jacques, J. T. Gabriel, H. J. Chapman, W. H. Young, F. J. Thorne, E. Hill, C. Winn, T. W. Bond, E. Ashworth, J. Douglas, F. Mason, S. Courtauld, and de Barri Crawshaw.

Mr. G. Day, gardener to H. F. Simonds, Esq., Beekenhams, contributed a small group of well flowered Orchids. The several plants were all in splendid health and quite clean. There were *Odontoglossums*, *Dendrobium Jamesianum*, *Cœlogyne cristata*, *Lycaste Skinneri alba*, and one or two others (silver Banksian medal). F. Knight, Esq., Thundersley House, Thundersley, sent a number of varieties of *Cattleya Trianae*, including specimens rather over average merit (silver Banksian medal). Messrs. L. Linden & Co., Brussels, exhibited *Odontoglossums crispum sunambulum*, and *Andersonianum Sehusterianum*; *Cypripediums insigne Luciani*, and *Weirtzianum*; and *Cattleya Trianae M. Linden*. Mr. J. Douglas, Great Bookham, staged a small group of cut Orchids which were very bright and attractive (silver Banksian medal). De Barri Crawshay, Esq., Sevenoaks, sent *Lælia anceps Amesiana* Crawshay's var., and *Odontoglossum erispum Imperatrice*. Messrs. H. Low & Co., Bush Hill Park, showed *Cypripedium insigne Sanderæ*, while several other growers contributed small exhibits.

CERTIFICATES AND AWARDS OF MERIT.

Acalypha Godseffiana (F. Sander & Co.).—A dwarf growing plant of decorative value. The heart-shaped serrated leaves are green with a cream margin (award of merit).

Apple Lady Pilkington (Southport Botanic Gardens).—A handsomely formed pale yellow variety. It is flattish round, higher on one side than the other. The half-open eye is deeply set, and the short stalk is embedded in a deep cavity. There is a flush of red on the sun side (award of merit).

Cattleya Trianae Ernest Ashworth (H. Holbrook).—A superb variety. The very broad fringed petals and the sepals are pure white. The handsome lip is maroon on the front lobe fringed with white, the throat being soft yellow, and the side lobes delicate blush (award of merit).

Cattleya Trianae Memora Linden (L. Linden).—The fine sepals and petals of this variety are bright rose, and the lip rich dark velvety crimson (award of merit).

Cypripedium Miss Louisa Fowler (J. Davis).—This is a distinct form, of which the parentage was not definitely stated. The dorsal sepal is green, with dark chocolate spots and blotches. The petals are deep claret, with darker veins, and the pouch lively claret (award of merit).

Cypripedium Weirtzianum (L. Linden).—An imposing flower. The dorsal sepal is white with dark lines, and the petals are similar in colour, with lines and spots. The pouch is blackish crimson (award of merit).

Lælia anceps Amesiana Crawshay's variety (de Barri Crawshay).—A magnificent variety remarkably rich in colour. The sepals and petals are white at the base, shading through rose to velvety purple crimson at the tip. The lip is rich blackish crimson, and the throat pale yellow with crimson veins. The outer portion of the side lobes is rich crimson (first-class certificate).

Lapageria rosea The Knoll variety (W. Bain).—This is in all respects an improvement on the well-known type (award of merit).

Masdevallia Curlei (no name).—This is a hybrid from a cross between *M. macrura* and *M. tovarensis*. The prevailing colour is creamy white (award of merit).

EELWORMS (NEMATODES).

BULLETIN No. 55 of the Hatch Experiment Station, Massachusetts, gives the results of a very extensive study of these pests. The following is a brief résumé of the bulletin:—

Nematodes are small worms allied to the earth worm. Many are entirely harmless, and only one species (*Heterodera radicleola*) is known to damage plants in Massachusetts. Many of the harmless species can withstand the winter, but the one which is so harmful to florists' plants is destroyed by freezing. It may, however, easily survive in the centre of compost or manure heaps which frost does not reach. It therefore follows that if soil, manure, and compost heaps are spread out so that every part becomes frozen no danger need be feared, provided the benches are not themselves infested. It would seem that the careful cleaning and whitewashing of benches and the use of soil which has been frozen would eradicate the pest. Of course the first potting from the cutting bench should also be in the soil which had been frozen, as the planting of infested plants or the contact of infested soil with the other would soon cause the whole bench to be infested, as the worms breed rapidly.

Infested plants usually appear sickly and gradually fade away and die. The roots of such plants are more or less covered with various galls or swellings. These are abnormal growths of the roots due to the presence of the worms, which, when full-grown, are not much larger than the size of a pin head. The damage to the plant is not due to the feeding of the worms upon the roots, but to the fact that the flow of the sap is checked by the abnormal growth. A plant weakened by the attack of these worms is quite likely to become infested with other insect pests and fungus.

The use of chemicals is of no value, as the eggs practically cannot be killed by such means. The most effectual, complete, and practical method of exterminating nematodes in greenhouses is by heating the soil by means of steam. The amount of heat necessary to destroy them is 140°, which is much less than has been supposed. As, however, all parts of the soil are not heated equally, it is recommended that it be heated to about the boiling point of water (212°).—("American Florist.")

THE PEOPLE'S PALACE HORTICULTURAL SOCIETY.

THE district of Mile End scarcely seems to be one in which flower shows are held, because in a general way we do not associate flowers with the East of London. Time was—and not such a great number of years ago, either—when there were acres of green fields within an easy walk of the Bank, now covered with bricks and mortar. There were little nurseries in the Bethnal Green, Mile End, and Whitechapel Roads, and some forecourt gardens in which a small bed of Tulips could be seen, also of Anemones, Ranunculus, and Pansies. The rural aspects have all departed, and when anyone travelling Stratford way comes upon a piece of green it is hideous in its blasted condition. Tree and shrub, hedgerow and green grass, are disappearing before the fumes of chemical and other works which have been reared. There are acres of desolation in Haggerston, Bow, Bromley, Canning Town, and Plaistow which have been bereft of every scrap of natural beauty. An advancing army of industrial agencies, necessary and useful in their way, are seen at work despoiling the face of Nature, and making the existence of vegetable life almost impossible.

Nevertheless in Mile End there is a flourishing horticultural society having for its object the encouragement of the culture of plants in what are known as the congested districts of the East of London—Bethnal Green, Mile End, Whitechapel, Stepney, Limehouse, Poplar, and Spitalfields. The People's Palace in the Mile End Road (a realisation in part of that bright vision sketched by Sir Walter Besant in his "All Sorts and Conditions of Men.") was opened in 1887, and has grown into an enormous educational and social force in the district. But it was felt from the first that something else was necessary to introduce a little of sweetness and light into the homes of the workers who so largely constitute the dwellers. Two or three University men from Oxford House, Bethnal Green, who had leanings towards the new socialism which has stirred so many sympathetic hearts lent their aid, and a society was formed with its headquarters at the People's Palace. The Duke of Fife was made President, and the first season, 1894, was opened by an inaugural address from Mr. Richard Dean, V.M.H., the horticultural adviser to the Society, the Marquis of Lorne presiding.

After four years' operation the Society held a kind of congratulatory dinner at The Three Nuns, Aldgate, on the 26th ult., Mr. E. Flower, M.P., one of the Hon. Secretaries, in the chair. Mr. Harold Boulton, his colleague, a gentleman to whom very much of the success of the Society is due, filled the vice-chair. In proposing as the toast of the evening, "Success to the People's Palace Horticultural Society," the Chairman sketched the operations of the Society during the past five years. A commencement was made in 1894 by holding two exhibitions; the aggregate number of entries was 239, and the prize money awarded £43. In 1895 three exhibitions were attempted, a spring show being added to the summer and Chrysanthemum shows held in 1894; the entries ran up to 741, and the prize money amounted to £60. In 1896 the same number of shows were held, with a somewhat similar result. In 1897 a Dahlia Show was added, making four; the entries were 1085, and £75 awarded in prizes. Last year there was the same number of exhibitions; the entries increased to 1439, and the prize money awarded £100. Unfortunately, through lack of funds, there is danger of one of the shows—the Dahlias—will have to be abandoned, which is matter for great regret, as Dahlias were cultivated in many of the little back gardens with considerable success. The Society is self-supporting and self-governing, but as the subscription is low the income from that source is small, and it is supplemented by donations from ladies and gentlemen interested in the work of the Society. The Chairman, after alluding to the suitability of the fine Queen's Hall of the People's Palace as a place for shows, went on to say the membership was now 510 strong, yet they were only at the beginning of the work. As he believed a great future was mapped out for the Society, they had started a children's section as a distinct organisation with every prospect of success, and were interesting the teachers of voluntary and Board Schools in the work.

The health of the Judges, Messrs. R. Ballantine, R. Dean, and T. W. Sanders, who give their services gratuitously, was given, and in responding, both Mr. Ballantine and Mr. Sanders alluded to the improvement in the exhibits seen every season. They particularly alluded to the culture of Chrysanthemums in little home-constructed houses, stating they were surprised in November last to notice the remarkable advance made in the production of specimen blooms.

In responding to the toast of the Hon. Secretaries, Mr. Harold Boulton alluded to the fact that on a few occasions Royalty had honoured them by a visit, and how gratified they were with what they saw. Testimony was borne to the valuable services to the Society rendered by Mr. C. E. Osborn, the Secretary of the Society, who duly responded to the toast of his health. The proceedings, which were throughout of an animated and enjoyable character, was brought to a close by the singing of "Auld Lang Syne."

LONICERA FRAGRANTISSIMA.—This is by no means a showy plant at any time, but it is one of the earliest flowering shrubs we have, and is also remarkable for its fragrance, which is diffused to a considerable distance, and resembles the common Woodbine. The first flowers were open here on the 24th ult., and it usually gives a succession of bloom during the early part of the year. It appears to be perfectly hardy, although a native of China, but I find it advisable to plant it against a south wall in order to get the flowers as early as possible.—W. H. DIVERS, Belvoir Castle Gardens.

NOTES ON ALPINE FLOWERS.

SEMPERVIVUM LAGGERI.

THERE are many positions in which the Houseleeks are invaluable, and their worth is not properly appreciated by those who are imperfectly acquainted with the variety of appearance they present. There are, of course, many very much alike, but a large number are dissimilar. In hot dry positions they are quite at home, drought having apparently no power to destroy them. Should they look limp and shrivelled for a time, they soon recover. For wall or roof gardening they are exceedingly serviceable, and on perpendicular rockwork they look well in the crevices.

Among the Sempervivums few are as interesting as what are known as the Cobweb Houseleeks. They are so called because of the silk-like tomentum with which they are covered, and which, in dry weather, looks as if it had been woven by a spider. It is remarkably pretty, and well repays close inspection. The Houseleek now spoken of—*S. Laggeri*—is, botanically speaking, only a variety of *S. arachnoideum*; but, for simplicity sake, the usual abbreviated name of *S. Laggeri* is here used. It is larger in all its parts than the small-sized *S. arachnoideum*, and is consequently more effective. The rosettes in dry weather are quite as white as the Edelweiss, and the red flowers give an effective contrast. No compost suits the Houseleek better than a mixture of clay, cow manure, and lime rubbish. In wet districts the Cobweb Houseleeks sometimes decay if planted on the level. They will be found in such places to thrive better if planted on the face of a wall or rockwork, and fully exposed to the sun. The smallest modicum of soil to start with will suffice to establish a rosette or two, and will not require to be added to as the plant increases in size. A small hole made in the mortar of a wall and filled with the compost recommended, will afford a home for this desirable and interesting plant.

SAXIFRAGA SALOMONI.

A specialist in Saxifrages has his work cut out for him should he endeavour to unravel the mysteries of their nomenclature. Seedlings seem to set at defiance all our preconceived ideas regarding species, and give us room for doubt, to say nothing of a stronger word. Thus, though we are told that the pretty little Rockfoil under notice is a hybrid between *S. Rocheliana* and *S. Burseriana*, one would require to know more about the manner in which the cross was effected than is at present at our command before we can accept the statement. However this may be, this Saxifrage is an acquisition, and is worthy of wider growth than at present. The little rosettes are rather like those of *S. Burseriana*, but softer-looking and greener in colour. The flowers, which are white, have more substance than those of the greater number of the forms of *S. Burseriana*, and are almost intermediate in size between those of what we know as the type of that Rockfoil and those of *S. B. major*.

So far as his own garden is concerned, and in the few other places the writer has met with it, *S. Salomoni* does not appear to have the failing which so militates against the usefulness of *S. Burseriana*. This, as is pretty well known, is that it dies off from the centre when it attains a moderate size. *S. Salomoni* is not yet plentiful, but is offered for sale by some nurserymen. It is increased by division.

SAXIFRAGA CERATOPHYLLA.

Recognised as a variety of *S. trifurcata*, the Horn-leaved Rockfoil may be conveniently spoken of under its garden name. It is a plant which gives much pleasure in winter, when its leaves are of brightest green, as well as in early summer, when its large white flowers are upraised above the foliage.

According to the soil *S. ceratophylla* grows from about 3 to 8 or 9 inches high. It forms large tufts of deeply parted leaves, which look remarkably pretty. The flowers are very freely produced in panicles, and are of almost snowy whiteness. It comes from Spain, and may be propagated by division or seed. In moist weather a "branch" taken off with the old stem attached, and put an inch or two into the ground, roots readily. The Horn-leaved Rockfoil will thrive either in sun or shade, but—like a good many of the Saxifragas—is the better of being renewed occasionally by propagation. In some gardens it dies off in a manner not unlike *S. Burseriana*. This distinct large flowered and leaved Saxifrage should not be omitted from collections of Alpine flowers.

ERYTHRONIUM HARTWEGI.

The brief space available may suffice for a short notice of the earliest of the Dog's Tooth Violets—*Erythronium Hartwegi*. It is a native of North-West America, and comes into flower with us about February. Newly purchased roots may bloom earlier, but, when established, early in the month named is its usual time. There are more attractive Dog's Tooth Violets, but its creamy-white or yellow flowers and mottled leaves seldom fail to please. It ought to have a rather dry and sunny position. With a view to securing flowers of more substance and lasting longer in bloom, the writer experimented with it in a half-shaded position with disappointing results. *E. Hartwegi* may be obtained at a moderate price from those in the trade.—ALPINUS.

(To be continued.)

PRIMROSES IN JANUARY.—As showing the mildness of the weather during January and the preceding month, in the woods here Primroses are bursting into flower. On the 19th ult. I picked several fully expanded blossoms.—E. MOLYNEUX.

THE YOUNG GARDENERS' DOMAIN.

GLOXINIAS.

THESE useful and beautiful plants when well grown fully repay all necessary attention, and will be finely proportioned, carrying deep green foliage and abundance of flowers. The following treatment has answered well. Plants raised from seeds are the best, and sowing should commence early in January. The pans must be drained and filled with a compost of fibrous loam and leaf mould in equal parts, with a liberal sprinkling of sharp sand. Peat should not be used, or the surface may become covered with a green moss, which is fatal to the roots of seedlings. The pots, covered with glass, should be placed in a warm house, and immediately the seedlings are large enough to handle they ought to be transplanted into other receptacles, using the same compost as before. If care be exercised in the moving and the soil is in proper condition the roots soon take hold, and the seedlings thrive, and must eventually be potted singly in well drained 3-inch pots. After this stage is reached a good place for them is the shelf in a Cucumber house close to the glass, and they demand careful watering. If convenient allow them to remain in this position until they show flower, and then remove them to a close pit until the flowers open. The grower will find it an advantage to flower the plants the first year, as he will know what he is growing, and can discard worthless and inferior varieties.

After flowering the supply of water must be gradually lessened, not drying suddenly, as that is the time the tuber is perfecting itself for the following season. When thoroughly dried, which will be in the early autumn, they should be removed to a shelf where they do not receive water, but where atmospheric moisture is afforded, the main object being to keep the tubers plump. Early in January the potting must be done and a little stronger compost may be used—viz., two parts of fresh fibrous loam, one and a half of decayed cow manure, one part of leaf mould, with an addition of sharp sand, placing the tubers in the same sized pots they previously occupied. They should then be placed in brisk heat until they begin to break freely, when they will soon require a shift into 5 and 6-inch pots. Place them back for a few days, and afterwards transfer to an intermediate house, keeping well up to the light. As soon as they have filled these pots with roots, they will require one more shift into their blooming pots, using the same compost as previously advocated. By this simple mode of culture they grow luxuriantly, with foliage covering the pots, and flowers of size, substance, and colour.—INTERESTED.

THE FIG.

(Continued from page 73.)

TURNING to the permanent trees, if ripe fruit be desired during the early part of May, a start should be made at the commencement of the year, giving a temperature of 45° by night and 50° by day, with a rise of 5° at the end of ten days, and when at the latter temperature, syringe the trees at midday in bright weather, using tepid water—this will assist an even break. At the close of the first month the young growths will be coming, when a temperature of 55° by night and 60° by day should be given. Endeavour must be made to keep the atmosphere of the house a genial one, care being taken in air-giving, allowing the temperature to reach its maximum, then admitting a little by means of the top ventilator, closing the house sufficiently early to make the best possible use of sun heat.

About the middle of February the young fruit will be swelling, and a further rise of 5° should be allowed. As growth advances stopping must be resorted to, pinching the points of those shoots which have four or five good leaves, and these again breaking, will give the successional crops of fruit. The shoots will require tying down, but do not do this too tightly, but allow room for further development of the young wood. In carrying out this work try to get all leaves clear of the glass, or those touching it may be scorched on bright sunny days. Maintain a clean healthy growth, by careful but thorough syringings, both in the morning and at closing time, the latter being performed sufficiently early, that all may be dry ere night sets in. If syringing is not properly done, red spider soon makes its appearance, and will prove very detrimental to the tree.

When the fruit commences the second swelling, which, if grown as advised, should be about the middle of April, allow the night temperature to range about 70°, by day 80° or even 85°, before admitting air. Admit air gradually until the maximum is reached, as, if given thoughtlessly, a wholesale crippling of the young tender shoots may take place. I have heard and read of shading being used for Figs, but have had no personal experience in its use. I have seen our Figs stand the hottest summer sun without it, and they have not been injured in the slightest. Scorching of the leaves is, I believe, more the fault of careless ventilation than otherwise. During the growing season, never allow the border to approach dryness. It is really astonishing the amount which is taken up by healthy vigorous Figs during a season of growth. I do not mean give a little and often, this is bad practice, but apply sufficient at each watering, to thoroughly wet every particle of the soil, and from their restricted position this is soon appropriated by the roots.

As the Fig is a gross feeder the plants must have stimulants, and there are so many good special manures nowadays that it is difficult to advise one above another; at the same time the Fig will be found to relish feeding from the "old-fashioned" liquid farmyard manure. As ripeness approaches discontinue feeding until the first crop is gathered. More air may now be admitted, and syringings should cease for the time, keeping moisture about by frequently damping the walls and floor. If required for immediate use on the dinner table, allow the fruit to droop somewhat, gathering just as a drop of the juice is observed in the eye, but for travelling gather slightly before this stage. In packing Figs

use shallow boxes, lining with wadding or some soft material; wrap each fruit separately in either soft leaves or tissue paper, and over this either wadding or fine wood wool. Place a single layer in the box, and fill all crevices between the fruit with the same kind of material as used for wrapping, placing a layer of wadding over all.

The first crop over, encourage the successional ones by growing as previously advised. During the period of ripeness red spider may have made its appearance, in which case syringe heavily for a few days. Wasps and bluebottle flies may be found very troublesome in the autumn months, and means should be taken for their eradication, as if left unmolested a whole house of ripe fruit is soon totally ruined. As the autumn months advance gradually allow the trees to go to rest, after which preparations are made for another year's work.—SEMPER.

HARDY FRUIT GARDEN.

Apricots.—As these are the first trees to bloom in spring the necessary pruning, cleansing, and tying-in should be completed as early as possible. It is usual to detach all the younger wood from the wall early in December for the purpose of retarding the buds and to complete the ripening. The branches may now be unfastened, which will facilitate the operation of removing worn-out and useless wood. Apricots are much subject to losing branches by gumming and other causes. When affected in this way it is desirable that they be removed, thus giving an opportunity to re-arrange the whole trees, laying in, and disposing the wood to the best advantage.

Apricots bear both on spurs and young ripened shoots. Natural spurs are formed more freely on Apricots than on Peaches and Nectarines, while artificial spurs may be produced wherever desirable by shortening shoots that cannot easily and profitably be laid in. Having pruned out all superfluous wood, shorten the young shoots to either a triple bud or a wood bud. Dispose the main branches in position, afterwards the secondary branches, and finally the bearing wood, the latter about 4 inches between each shoot, which ought, as far as possible, to originate from the upper side of the branches. Well wash the walls and trees with an insecticide before re-arranging the branches. In painting the young shoots with the mixture due care must be taken to work the brush upwards so as not to dislocate the buds.

Peaches and Nectarines.—The pruning, cleansing, and re-arrangement of these should be dealt with next. The best fruit being borne on young wood, the aim in pruning must be to retain all the medium-sized, well-ripened shoots. Cut out weak and over-sappy shoots—the latter especially—starting from main branches. Partially worn-out branches ought to be removed, as well as weak wood wherever situated. It is seldom necessary or desirable to form artificial spurs on Peaches and Nectarines, though such will bear fruit readily. Thin out the young shoots to about 4 inches apart, retaining those of medium strength and well-ripened condition. Dress the walls, branches, and young wood with an insecticide, any of the numerous advertised compounds being effectual, though one formed of soft-soap and sulphur is excellent; 3 ozs. of soft-soap dissolved in a gallon of water, mixing a handful of sulphur into a paste and then adding to the above, will give a good insecticide. Some prefer to thicken it with clay, soot, and cow manure, applying it with a brush to the trees, but avoid injury to the buds on the young shoots by brushing upwards carefully.

In the final nailing-in of the young wood prune the shoots back to wood buds or triple buds, one of which is a wood bud. If pruned to flower buds only there will be no growth for drawing sap to the fruit. Superfluous growths which have to be dispensed with should be cut out entirely, or only sparingly retained to form spurs by shortening back. Secure all wood in a straight direction if this can be done readily.

Liquid Manure for Fruit Trees.—There is no better way of adding to the fertility of the soil in which large old fruit trees are growing, and which require assistance, than frequent applications of liquid manure from cesspools and tanks. The soil in most districts is now in a thoroughly moist condition, and liquid manure if applied will permeate down to the lowest roots, which will receive benefit as well as those in the upper stratum of soil. Liquid manure contains plant food in solution, and the value of rich material of this kind stored in the soil for the future use of the roots is exceedingly great. The liquid should be applied over the whole area of soil covered by the branches. It may be given freely to all trees which have previously borne good crops, and hence need assistance to sustain them for future effort.

Weakly growing trees will be stimulated by a copious soaking of liquid manure into making better growth, and plumping insufficiently fed fruit buds. Trees on grass suffer from exhaustion by reason of the grass largely abstracting food which is not replaced except by heavy manurial dressings either of liquid or solid material. The best manner of applying liquid manure on grass land is to make holes with a crowbar to a considerable depth, repeatedly filling them up with liquid until the soil is well saturated. When finished the holes may be filled in with manure and loam. In addition to filling the holes with liquid the latter may be poured freely on the surface.

Bush fruits, including Currants, Gooseberries, and Raspberries, much appreciate the rich fare contained in liquid manure, and it may be applied freely to well-established bushes, either previous to or after a mulching of manure. The fibrous roots of these small fruits appropriate large quantities of food, and it is profitable to treat them liberally when in a good fruiting condition.

Young trees when planted in well-prepared and rich soil grow freely enough, and should not have an application; but weakly bushes in poor soil would certainly be benefited.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest House.*—The trees started in December, and having set the fruit, should be syringed in the morning and afternoon of fine days to keep red spider in check, but an occasional syringing suffices in dull weather, damping the paths and borders instead of the trees, so as to maintain a genial atmosphere. Applications of liquid manure will assist the fruit in swelling, especially that on trees long subjected to forcing. Vigorous trees will not require any stimulants, excessive vigour being unfavourable to the fruit safely passing the stoning process. Proceed with the thinning of the fruit, removing a few fruits only at a time, those badly placed first. Follow up disbudding, leaving a growth at the base of each bearing branch or last year's wood and another at its extremity, or at a level with the fruit. The shoots retained for attracting the sap to the fruit should be stopped at the second or third leaf unless they are extensions, but the basal growths must be trained-in to take the place of those bearing fruit. Shoots upon extensions may be left at 12 to 15 inches distance apart to form the bearing shoots of the future. The night temperature may range from 55° to 60°, and 60° to 65° by day, with an advance to 70° or 75° from sun heat. It is better, however, to seek advancement from sun heat than to push the trees in sunless weather. Ventilate on all favourable occasions liberally, and avoid a close, stagnant atmosphere at all times, leaving a little air on constantly; but cold draughts are pernicious, and aridity favours insect pests.

Second Early House.—Trees started at the new year will be in blossom, and should have a temperature of 50°, 45° or even 40° on very cold nights, 50° to 55° by day artificially, and 60° to 65° from sun heat, not allowing a rise above 65° without full ventilation. Lose no opportunity of admitting air, ventilating from 50°, avoiding, however, cold currents, and leave a little ventilation constantly at the top of the house. Damp the paths and other surfaces occasionally to secure a genial atmosphere, but avoid a close saturated one. Shake the trees on fine mornings to disperse the pollen, or brush the blossoms over lightly with a rabbit's tail mounted on a small stick, or apply the pollen to the stigma with a camel-hair brush.

Houses Started Early in February.—The trees to afford ripe fruit in July must now be started, they having commenced to swell their buds naturally. Syringe the trees occasionally until the blossom buds show colour, when it should be discontinued, but sprinkle the paths and borders once or twice a day to maintain a genial condition of the atmosphere, avoiding a close, stagnant one. If the flowers are very numerous thin them by rubbing the hand downwards on the under side of the shoots, which will strengthen the remainder, enabling them to set better. Examine the trees closely, and if there be any aphides, fumigate with tobacco or vaporise with nicotine, so as to destroy them before the flowers expand. Maintain a temperature of 40° to 45° at night, and 50° by day, above which ventilate freely. When the flowers expand raise the temperature to 50° at night, 55° by day, and 60° to 65° from sun heat with free ventilation. On cold nights the temperature may fall to 45°, or even less, also 50° by day, allowing a little ventilation constantly at the top of the house.

Later Houses.—Admit air freely so as to retard the blossoming, especially in the case of unheated houses, which are liable to suffer from spring frosts. See that borders have water if needed. If the roof-lights have been removed they need not be replaced until the buds are advanced in swelling; they are quite safe for another month or more, or until the blossoms show colour.

Pines.—*Fruiting Plants and Starters.*—The specially prepared plants for early summer fruiting will now be throwing up fruit, and should have a mean temperature of 70°, varying it 5° according to the weather, admitting air at 80° with sunshine, but not lowering the temperature, allowing it to rise to 85°, closing between that and 80°, and if it rise somewhat after closing it will be an advantage rather than otherwise. When the suckers are large enough to handle, all except one to each plant must have the growth checked by taking out the centres.

Successional Plants.—To supplement the autumn-potted plants, select others which have been wintered in 7 or 8-inch pots, choosing the most vigorous. Those remaining may be reserved until the general spring potting, when they can be shaken out and treated similarly to suckers. For those now to be potted good fibrous loam, with the turf well reduced, placed under cover to become dried, is a suitable compost. Drain the pots well, dust soot or dry wood ashes over the crocks to exclude worms, and ram the soil firmly round the plants, keeping them well down in the pots to admit of copious supplies of water being given when necessary; 10-inch pots are suitable for Queens, and 11 or 12-inch for those of more robust growth. A temperature of 60° to 65° will be sufficient for these plants, also for those potted last autumn, and about 85° bottom heat. Plants in beds about to be started into fruit must not have the heat at the base of the pots over 90° or 95°, or their roots will be injured. If sufficient fruit be started to meet the requirements, later successional plants that have not been subjected to a high temperature may be advanced slowly, they with autumn-rooted suckers requiring careful watering, especially where the heat at the roots is supplied by fermenting materials.

THE BEE-KEEPER.

SKEP OVERTURNED—DRONES IN HIVE.

DURING the night of the 18th ult. I had a skep containing a swarm of 1898 overturned by the wind; the combs being severely fractured, the skep old and in bad condition. I got together four combs of stores and placed them into a frame hive. This and the skep containing the bees were taken into a warm room, and on my lifting the skep, which was placed close to the entrance of the frame hive, the bees entered the latter readily, including the queen. I then took the best piece of comb which had a little store at the top and tied it in a frame, and widening the four frames containing stores placed the empty one in the centre for the bees to cluster on. The hive was left all night in this warm room, and next morning all seemed well, so I put on plenty of warm covering and removed the hive to the same stand that the overturned skep occupied. As a novice, I should like to ask your bee correspondent if there is anything else that can be done; and as this skep was meant to have been transferred to a frame hive later on, would not it be preferable to do it now instead of waiting until spring, when much brood will have to be sacrificed? Of course, one would not always be in a position to supply four frames of sealed stores; but supposing we had them, and a comb of drawn foundation, and a warm room (65° to 70°) for operating, would not transferring now be more desirable? I may say that we lost from twelve to twenty bees during the operation, and neither myself nor man was protected, and we only received one sting each.

I should just like to ask one more question. On taking a frame from one of the well-stored hives I saw a drone, and on examining found several, also drone larvæ here and there, and as this hive had a young queen supplied last autumn what is wrong, and what is to be done? I take it that the hive is queenless, and has a working bee ovipositing, which is naturally a drone breeder. The stock in question is very strong in numbers, and had a young queen supplied in October.—NOVICE.

["Novice" is to be congratulated for the ready manner in which he overcame a somewhat difficult operation. Many apiarists, who do not consider themselves novices in bee management, would have hesitated before attempting to transfer bees from a straw skep to a frame hive at midwinter. Had the bees been left to take their chance in the skep in the case recorded above they would probably have succumbed before the spring, as the combs were broken down, which shows that it is sometimes an advantage to leave the beaten track and judge each case on its merits.

The only fault we have to find with "Novice" is that he did not go far enough. Instead of tying only "the best piece of comb into an empty frame," it would have been much more beneficial to the bees in the future if the whole of the combs had been transferred with the exception of that containing drone cells. It would then not have been necessary to disturb them again. All that is requisite is a few pieces of narrow tape or raffia. We prefer the former for winter, as it would probably have to remain tied round the combs for a couple of months, whereas if transferring is done in the summer or early autumn the ties may be removed within twenty-four hours. Have them of sufficient length to go round the bottom of the frame so that the ends are fastened at the top. Fill the frame with the best pieces of comb, taking care that the cells slope upwards the same as they did in their original position. With a little practice the combs may be placed firmly in the frames, so that they will require little attention from the bees, as they would be unable to fasten them securely at midwinter.

There would probably be sufficient combs in an ordinary skep to fill four frames. Were these placed in the middle of the hive, and the four frames of stores on each side, with plenty of warm coverings, as has already been done by "Novice," no further attention would have been necessary until the brood chamber required enlarging.

We do not recommend any interference with the bees at present, as the temperature is now lower than at any time during the winter. There will be ample stores in the hive for at least two months, as the bees will be able to cluster on the piece of comb inserted in the empty frame. If bees can possibly avoid it, they will not cluster on sealed stores, owing to the surface being so cold. It therefore shows the advantage of having some spare combs for an emergency like the above. The spare combs from the skep may be fastened into frames in readiness for future use, to be afterwards stored in a dry place. By working on this plan the brood will not be sacrificed, as suggested by your correspondent, as the frames may be placed in the hive when necessary in the spring.

Without a doubt the stock having drones and drone larvæ at this season will either be queenless, or the queen is injured and unable to fulfil her duties. At various times we have had several cases similar

to the above, principally with stocks having young queens introduced the previous autumn. More often than otherwise the queen has been dead, but we had one interesting exception a few years ago. Some drones were observed on the wing during early spring, and on examining the stock a fine queen was observed, but not any brood; they were fed with thin syrup for a fortnight, but this had not the desired effect, and after experimenting for several weeks the queen was destroyed, and the bees were united to the two stocks nearest to it on the stand. This is what we should advise "Novice" to do, as soon as the weather is warm enough.

Bees that have been queenless for some time will often ball the queen when united to another stock. It is therefore advisable to cage the queen for a few hours, and unite the bees in the usual manner, either by sprinkling them with flour, or by placing the combs alternately without disturbing the bees.—AN ENGLISH BEE-KEEPER.]

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Ivy Leaves Eaten (J. C. B.).—The Ivy leaves appear eaten by some animal, and from the gnawing on the part of the larger leaf on the specimens, which has the veins left in part, we think by some larvæ, such as the night-feeding caterpillars, those of the "old lady" moth (*Mania maura*) feeding on Ivy, though the yellow underwing, dart, angle-shades, and other winter-feeding moths (by their larvæ) are sometimes not particular as to food plants. Whatever the enemy, we think it would yield to spraying the Ivy with Paris green paste, 1 oz. to 12 gallons of water, it sufficing to just coat the leafage with a thin film of the poison, applying when the foliage is perfectly dry. Of course, the Paris green will destroy or injure other animals partaking of the leaves, therefore judgment must be exercised, so as not to affect domesticated animals or those it may be desirable to protect from injury, such as rabbits, which are very fond of recently planted Ivy. The paraffin preparation named in answer to "Dorset" acts well as a deterrent, diluting to 3 gallons, and applying by means of a syringe. Perhaps you would find the marauders at work if you were to examine the Ivy after dark with a lantern, especially if caterpillars, though these may have passed into the pupa state, when they may be found in the ground in earthen cocoons, and an inch or two beneath the surface.

Black Currant Shoots with Big Buds (T. G.).—Your specimens represent a severe attack of the Black Currant bud mite (*Phytoptis ribis*). If the whole of the buds are in the same condition as those sent, there is nothing for it but to lift and burn every one of the bushes, and heavily lime the ground. Procure new stock from a perfectly reliable source, and plant as far away from the old plantation as you possibly can. Had you picked off the swollen buds when they were first noticed three years ago, the evil might have been mitigated.

Paraffin Emulsion for Mealy Bug on Vines (Dorset).—Softsoap, 5 ozs.; paraffin oil, one wineglassful, or 2 fluid ozs.; soft water, 1 quart. Dissolve the softsoap in the water by boiling, and, when dissolved, remove from the fire for safety, and add the paraffin at once, stirring briskly with a switch formed of twigs from an old birch broom until thoroughly amalgamated. For use, dilute with four parts of boiling or hot water, and apply with a brush at a temperature of 130° to 135°, reaching well into every angle, hole, and crevice. The preparation is best applied hot, but it answers when lukewarm, 90° to 100°, or even cold.

Material from Sewage Works (Chatham).—The article is that usually obtained by the precipitation of sewage, and in the ordinary cake form. Its value as manure is not great, certainly not more as a general rule than one-fourth that of well-decayed farmyard or stable manure, and some farmers do not rate it as high as that, while others consider it has considerable value for their crops. We have found it serviceable for general garden crops, especially where a course of manuring has been followed for some time, mainly consisting of stable or farmyard manure. It would be worth the price stated, and even more if the bulk is equal to the sample.

Manure from Horses Fed on Carrots for Mushrooms (E. B.).—The droppings are best from horses fed on upland hay and Oats only, the hunting stable horses affording the driest and best article; but unless the Carrots are used to such an extent as to cause the droppings to be soft and watery we have not found them materially to affect the production of Mushrooms, the precaution being taken to use the material a little more strawy, but short and well intermixed. Of course, the other description is the better, yet it is often a question of utilising material to hand rather than having it "cut and dried" for every purpose.

Temperature for Forcing Pit (Idem).—The plants—*Spiræas*, bulbs, and *Roses*—should be forwarded gently, commencing with a temperature of 45° to 50° at night, and the latter by day in severe weather, 55° in mild weather, advancing to 65° with sun, and some ventilation from 50° to 55°, and full at 65°. On fine days the temperature will rise much higher, but being from sun heat and the ventilation free, it will be an advantage rather than otherwise. Even with the temperatures quoted the bulbs must be kept well up to the glass or they will become drawn, and the other plants cannot have too much light to insure sturdy growth and development of the flower buds (now containing the flowers in embryo) into vigorous well-formed blooms. At this time of year we accord the plants the usual greenhouse temperature of 45° to 50° by artificial means, admit air at the latter, but not so as to lower the temperature. We maintain from 50° to 65° in the daytime, having the ventilation full at 65°, and from this point reducing it as the sun heat declines, closing for the day between 50° and 55°. The results are much better, though the time taken is longer, than by hard forcing, the plants being far more useful and lasting for decorative purposes.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (*Pomona*).—1, Yorkshire Greening; 2, Roundway Magnum Bonum; 3, Golden Noble; 4, Ribston Pippin; 5, Dumelow's Seedling. (*E. S.*).—1, Catillac; 2, Verulam; 3, London Pippin. (*R. P. W.*).—1, Scarlet Nonpareil; 2, Baxter's Pearmain; 3, Reinette de Caux; 4, Bess Pool; 5, Blenheim Pippin; 6, Golden Winter Pearmain. (*J. J. P.*).—1, Chaumontel; 2, Josephine de Malines; 3, Belmont.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than

six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. G.*).—1, *Catasetum citrinum*; 2, *Cœlogyne ocellata*. (*Fernale*).—*Asplenium fontanum*. (*P. F. H.*).—1, *Euonymus japonicus variegatus*; 2, *Escallonia rubra*; 3, *Acacia dealbata*; 4, *Polystichum angulare*; 5, *Asplenium flaccidum*. (*Evergreen*).—1, *Juniperus recurva*; 2, *Cedrus Libani*; 3, *C. deodara*; 4, *Thuia occidentalis*; 5, *Cupressus torulosa*; 6, *C. Lawsoniana*, varietal form. (*S. H. G.*)—1, *Curculigo recurva*; 2, undeterminable without flowers; 3, *Adiantum tenerum*.

ADVANCE, IRELAND.

On the 19th of January of this year we wrote a paper on a perennial subject—*i.e.*, milk and butter. More has been said on our shortcomings with regard to these two articles than would fill many a large volume. We are told by our advisers to grow more milk and less corn, but we are not told how to do it—that is, to make it pay. We are of opinion that a good deal of milk-producing at present is not attended with gigantic profits. Our restrictions are many, and they appear to be increasing.

We are told to make better butter, and also more of it, though if we sell our milk we hardly know where that is to come in. We are told that if we make better butter we shall get better prices for it. How will the consumer like to give more? Would not an enhanced

price cause him to turn his attention to margarine, or some other substitute?

We heard it said years ago, when trade was better and the farmer prosperous, that butter at 1s. 6d. per pound left nothing for the farmer; we heard the same fact stated only the other day; and as butter during the last year has with us never reached 1s. 6d., we want to know what encouragement there is to make butter at all? We cannot do as isolated units. By that we mean it is not a bit of use for each individual farmer to make his own few pounds of butter, and expect to sell them at a profit, unless he lives quite near either some large and thickly populated centre, or can persuade the resident landowner or parson to take his produce at a fancy price, but this latter is not legitimate trade.

We spoke of "co-operation" as it is found in Ireland, but we had not much data to go upon. Since then a kind friend who has access to figures has furnished us with some useful particulars, which we gladly place before our readers. We must say, as some editors do, we are not responsible for the accuracy of these figures, nor do we altogether endorse all our friend says. The panacea for distressed Irish agriculture will not quite fit in for English ideas. The scheme in the main is good, and parts of it, like the curate's bad egg, are very good.

Ireland's distress was Mr. Horace Plunkett's opportunity. Being an Irishman and member for co. Dublin, also Irish Privy Councillor, he was made a Commissioner of the Congested Districts Board, and his attention was turned to find some method to relieve and permanently help the crippled industry. As early as 1889 he began to promote agricultural co-operation, and in 1894 he founded the Irish Agricultural Organisation Society. He thought this a better plan than hammering away at a scheme for lowered rents. And so it is, and under his management the project appears to have made a really excellent start, we were about to say, but that is hardly correct, as co-operation appears to have taken firm hold, and "goes" well.

These co-operative societies number 243, having a total membership of 27,322. Of these 136 are purely dairying, seventy-seven are agricultural, fifteen credit societies, and thirteen miscellaneous home industries and poultry societies, with two trade federations for the sale of produce and purchase of requirements.

Now, as to the cost of these co-operative dairies—£700. £1000 in £1 shares are issued. A farmer pays 10s. in cash, the other 10s. in milk. The milk is separated at once, the separated milk being returned to the supplier, and the rate of payment is per butter fat. It is said the farmers are receiving material pecuniary benefit, especially those who are shareholders as well as milk sellers. We fancy these farmers must be men in a very small way of business if they can only manage to take shares in the proportion of one per cow, and can only pay 10s. per share in cash.

There is one fact to which we take exception. Speaking of the creamery butter, "There is one especially instituted agency of one-third of these creameries that would effect sales of over £150,000 last year, and *therefore probably approaching half a million for the whole development so far attained.*" The italics are our own. No. This agency is doubtless the best. If the others are as good, why are their deeds passed over in silence? It does not in the least follow that the other two-thirds can make up the rest of the half million. The argument is founded on a false basis.

We thoroughly believe in associations for the purchase of manures and feeding stuffs, but these things have been done some time in England, though in perhaps a different way. We have been intimately acquainted for the last thirty-five years with the working of certain mills, registered as limited companies, the shares of which are almost entirely in the hands of farmers, and the management in their hands too. These mills were built for the sole purpose of supplying the owners with pure feeding stuffs and guaranteed manures.

This course was forced upon them by the trickery of traders, and they have no reason to regret the step they took. The shares certainly were more like £10 than 10s., and the dividends have run as high as

£10 per cent., we believe once they reached 16. Through fair weather and foul the average has been 6 per cent.; this is a good investment, to say nothing of the benefit derived from unadulterated cakes and tillages.

We know something, too, of the Credit Bank workings, as we have one established in our midst. We ask a trifle higher per-centage than these Irish banks. They are content with 5 per cent., we can readily get 6. We do think these banks ought to be more general; it only wants a setting about, and the thing is done. Our correspondent says—"It is stated that the saving by wholesale buying of manure, guaranteed and analysed, has been enormous." Well, if we make it ourselves, or even buy it as the Englishman does at so much per unit, we think the Irishman does not go one better.

WORK ON THE HOME FARM.

There is plenty of water about now, and where the land is not absolutely flooded it is not in a fit state for horses to walk on, much less to plough or work with any probable benefit. The possible exception is old lea not yet ploughed for spring corn. We have one such field, and the ploughing is finding occupation for the horses until, as we hope, drier conditions shall make other work possible.

Whatever the weather may prove, there is one job that must be done—muck must be removed from the yards. We have raised the cribs again and again, and the only next alternative is to lower the manure. Should not we rejoice in a week's frost?

Potatoes keep up the moderate level of price with which they opened the autumn campaign; 2s. 6d. per ton would cover the fluctuation of price. Large quantities have gone into consumption, especially of the higher qualities from the best districts, and there is a distinct ground for hope of a rise if frost were to step in to check the supplies of green vegetables.

Considering the much greater advantage to which offal Potatoes can be put in autumn, and the loss of weight and waste of the ware incidental to holding them over until spring, it is really almost surprising that growers can be found who will thus accommodate the consumers; but a rise of £2 or £3 per ton once in four or five years is sufficient to keep alive the speculative spirit, even in the matter-of-fact and cautious farmer. The Potato grower is now quite the speculator of the agricultural world, for the dead level of grain prices has long ago knocked out of it all hoarding-up of old Wheat.

Notwithstanding the open weather stock markets are very much depressed. The light Turnip crop is the only possible reason to account for this, but as young Clovers are a good plant there should be plenty of summer food, and the approach of spring will give graziers confidence to buy as soon as they can realise that winter is past. But is it past? Hardly; for there has been none. Is it still to come? Perhaps; but farmers generally will benefit most by its absence.

Springs are now ample, and we trust that water difficulties are settled.

OUR LETTER BOX.

Bacon Curing (T. H.).—You will find the information you require on this subject on page 430 of our issue of December 1st, 1898. This you may procure from the publisher, 12, Mitre Court Chambers, Fleet Street, London, for 3d., post free.

REMARKS.

22nd.—Windy, with alternate cloud and sun; brilliant night.
 23rd.—Overcast and rainy till noon; fine and dry after, with a gleam of sun about 3 P.M.
 24th.—Fine and colder, with generally clear skies.
 25th.—Almost cloudless day and night.
 26th.—Almost unbroken sunshine by day, and bright night.
 27th.—Almost cloudless throughout.
 28th.—Bright almost all morning; occasional cloud after noon.
 A fine week with average temperature.—G. J. SYMONS.

CHOICE FLOWER SEEDS.

- Barr's "Prize Strain" Single Begonia.—Saved from the finest colours and best formed flowers. Per packet, 1/6, 2/6, and 3/6.
- Barr's "Prize Strain" Double Begonia.—Saved from the highest quality flowers. Per packet, 2/6 and 3/6.
- Barr's "First Prize" Calceolaria.—Saved from the finest selected flowers and richest colours. Per packet, 2/6 and 3/6.
- Barr's Extra Choice Mixture Carnations.—Saved from the finest double flowers of the highest class. Carnations and Picotees, per packet, 2/6.
- Barr's "First Class" Cineraria.—A select, comparatively dwarf strain, saved from largest flowers of finest form and best distinct colours. Per packet, 2/6 and 3/6.
- Barr's Superb Mixture Gloxinia.—Saved from the finest sorts. Per packet, 1/6, 2/6, and 3/6.
- Barr's "Covent Garden" Choicest Strain Primula.—A very select strain, flowers of the finest colours, and of good substance. Per packet, 1/6 and 2/6.
- Barr's "Covent Garden" Primula White.—Flowers large and handsome. Per packet, 1/6 and 2/6.
- Barr's "Covent Garden" Primula Crimson-scarlet.—A magnificent strain of richest colour. Per packet, 1/6 and 2/6.
- Barr's Select Blue Primula.—The finest blue variety in cultivation. Per packet, 1/6 and 2/6.

BARR'S SEED GUIDE contains a Select List of the best Vegetable Seeds and most beautiful Flower Seeds. It is full of Practical Hints, and will be found of great value to Gardeners, Amateurs, and Exhibitors.

SENT FREE ON APPLICATION.

BARR & SONS, 12 & 13, KING STREET, COVENT GARDEN, LONDON

ANT. ROOZEN & SON'S

CHOICE

VEGETABLE & FLOWER Seeds

FOR PRESENT SOWING, AND

No. 972.—VOL. XXXVIII., THIRD SERIES.

NOVELTIES

RAISED AT

WINDSOR AND OSBORNE.

It is Messrs. CARTERS' privilege to offer the following new and choice productions to the notice of gardeners and private cultivators.

BRITISH QUEEN MELON.

Raised and named by Mr. OWEN THOMAS, Supt. of the Royal Gardens, Windsor. Awarded the First-Class Certificate R.H.S. Pronounced by the Committee to be not only the very best white-flesh melon ever submitted, but the richest flavoured of any colour. Awarded the Gold Medal of the Royal Caledonian Society in association with other fruit exhibited by H.M. The Queen.

In sealed packets, price 2/6 and 3/6 each, post free.

ROYAL OSBORNE CUCUMBER.

A valuable cross between the Rochford and an improved type of Telegraph, raised and named by Mr. GEORGE NOBBS, Head Gardener to H.M. the Queen at Osborne. In our opinion it is one of the best all the year round varieties introduced in recent years.

In sealed packets, price 2/6 & 3/6 each, post free.

ILLUSTRATED CATALOGUES, POST FREE.

WE HOLD THE ENTIRE STOCK OF SEEDS OF THESE TWO NOVELTIES.

CARTERS,

The Queen's Seedsmen.

Only Address—

237, 238 & 97, HIGH HOLBORN, LONDON.

The 32nd Edition is Now Ready.

200 PAGES.

150 ILLUSTRATIONS.

PRICE SIXPENCE, POST FREE.

(By Parcel Post—it is so large).

EVERY AMATEUR SHOULD POSSESS A COPY.

AN ABRIDGED EDITION OF OUR CATALOGUE CAN BE HAD FREE ON APPLICATION.

CHRYSANTHEMUMS.

Our Stock is perfectly clean. We never had Rust or Disease in our Collection. Cuttings from 1/10 per dozen.

SWEET PEAS.

All Standard Named varieties are offered per 1/2-oz. Packet. From 3d. per Packet.

SEED POTATOES.

These are quoted in small lots, and Carriage Free to destination.

Journal of Horticulture.

THURSDAY, FEBRUARY 9, 1899.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

YOUNG MEN'S DREAMS.

FROM time to time we receive letters from correspondents, of whose capacity and means we know nothing, in search of advice as to how they may succeed in gardening. The majority of these letters appear to come from young men who have passed from school to a year or two of studentship in some institution or other in which "horticulture is taught;" or have been pupils for a short term in an establishment in which fruit or other products are grown under glass for supplying the markets.

Generally the inquirers commence by stating, what is no doubt quite true, that they have a strong inclination to follow gardening as a means of livelihood, as it appeals to them as such a pleasant and interesting occupation; and as they have had a little experience, and have command of a small capital, they wish to know how to invest it, no doubt with a view to making a fortune in the course of a few years.

It is very rarely indeed that the actual extent of their "little" experience is narrated, and not once have we had an interpretation of what is meant by a "small" capital. It is conceivable that there are gardeners who, if in possession of a couple of hundred pounds, would not consider the amount particularly "small" to start with, while there are students and pupils who would regard five times that amount as a very small "dot" indeed. In the absence of anything approaching precise knowledge on those essential points, and of credentials as to natural aptitude for the work in which they desire to engage, devotion to duty and habits of industry, we can only give a brief line of advice in the stamped directed envelopes, which are usually enclosed for replies.

Than being helpful to persons who are earnestly desirous of obtaining proficiency in the craft, we have no greater pleasure; but we have to be honest, and this compels us to say that the greatest kindness we could do to some aspirants, who have made a start in gardening, would be to help them out of it. On the other hand, it is especially gratifying to see men now thriving, who in their

probationary days entered with heartiness into whatever work was set them to do, who did not shrink from the drudgery of labour, and who went perseveringly on step by step through section after section; who lost no opportunity of acquiring knowledge—theoretical and practical—to equip themselves for the contest with men of strength, and each year getting stronger and more numerous, for industrial supremacy.

These are the young men who win—men who concentrate their studies on these particular subjects that are the most likely to be of service to them, and then apply the knowledge obtained sedulously and untiringly—or, in other words, educate themselves to become both clear, sound thinkers, and skilled workers. They then not only know what should be done, but who can show the way to do it in the best manner. Men who have for a time to rely on their own mental and physical activities are just the men to make the greatest headway; and they are also the most capable of extracting the best services from others whom they may eventually have to control.

An episode once recorded in the *Journal of Horticulture* by a fine old gardener, Robert Fish, will enforce this point. Hearing what he called a “pretty quarrel” between a mistress and her maidservant, the latter, stung into casting what she thought a withering reproach, declared, “I took you for a lady; if I had known you had previously been a servant I would never have served you, that I wouldn’t.” Probably the mistress knew too much, and possibly may have expected too much; but be this as it may, a gardener cannot know too much practically as well as scientifically, but especially practically, for achieving the greatest success in either a private or a commercial establishment.

For obtaining a rich store of knowledge of the right kind is a question of diligence, and not that alone, but also of time. It cannot be purchased by sending young people for a year or two of studentship at an institution or in a garden or nursery. At the best, and the teaching may be good, such a course of instruction can only be regarded as preparatory, and much further experience is requisite before a man (or woman) can become in any sense a creditable gardener, while as to starting such fledglings in business, it would in nine cases out of ten amount to throwing away money.

So far as regards the supply of private gardeners, we suspect it will, under what may be termed natural conditions of increase, always exceed the demand; and we are convinced that the best course of training for well educated, studious, and prudent young men is to be found in the well-equipped and ably managed gardens that are happily found over the length and breadth of the land. As to the training of others who are fascinated by the charms of gardening, but have not been “brought up” to the calling: Some may be expected to succeed, and a few may even establish lucrative businesses, but it is practically impossible that anything like all can be winners in this lottery of life, and we very much fear that bitter disappointment will be the lot of many.

The gardening of the future appears to float before the vision of those who see it, or think they see it, as a golden dream, and that they have only to make their desire known to find a happy position within, to them, the charmed domain. Little do they know of the actual facts—of numbers of well trained young men seeking in vain for positions which they are competent to fill; and of men no longer young—men of character and ability, groaning under 12s. or 15s. a week, in nurseries, waiting for appointments month after month, and waiting in vain.

As an example of the feeling which seems to exist that gardeners are scarce, and that a highly respectable and worthy young man has only to hold up his hand to have his services competed for, a few remarks from one of many similar letters may be cited as follows:—

“I should be glad of your advice on ‘fruit growing under glass’ and gardening on a private estate, such as is carried on at Petworth Park and such places. I have been a pupil in a market nursery for eighteen months, and, I think, have a fairly good knowledge of a market nursery to be obtained in so short a time; but I have been advised by two or three people to give up the idea of this business branch and take up the other I mention. I should be glad if you could tell me what you think of fruit growing for market. I should have, when ready to start, very little capital, and think that this is a great thing in fruit growing. With regard to private gardens, I have been trying to obtain a start for the past year, but without success. I have been advertising lately, but only had one reply in a fortnight, which was no good. I feel sure that I am not going the right way to work, and should be glad if you could tell me if I am advertising in the proper paper, or give me any other advice.”

The writer of the above letter may be a man of energy, and he evidently has confidence in himself to think that “very little capital is a great thing” in starting in the business of fruit growing. From one point of view it suggests a possible advantage—namely, in there not being very much to lose. What we should think very much better would be at least thrice the amount of experience, and letting the capital grow till half of it would suffice for a start, leaving the remainder for extension if the beginning proved satisfactory.

What could be said in reply to such a letter than that in the absence of friendly influence for gaining a start in a private garden, the chances of its writer attaining his object were extremely remote; that young men with years of training would naturally be preferred for filling vacancies in gardens; that “Petworth Park and such places” were only filled by men of wide experience and strong recommendations; that he has not had half enough experience in even one section to master it; and that inclination, however strong—even amounting to devotion, *plus* enthusiasm—cannot compensate for lack of experience.

These are our convictions, and in the interests of dreamers, as well as in those of experienced men, we do not hesitate to make these convictions widely known. To think, as some excellently disposed people appear to think, that by payment of a fee, no matter of what amount, good men worthy of the name of gardener can be sent into the world after eighteen months’ or two years’ tuition is, in our opinion, one of the greatest fallacies of modern times.

PEACHES AND NECTARINES.

THE Peach, we are told, originated in Persia, but I am not going to dwell on that, for we all know it does well in this country with the protection of a wall. In outdoor culture aspect is the first consideration. A good south wall is the best, if available; if not, a west, or even east, if not in too elevated position, where the trees would catch the cold winds which are so disastrous in early spring.

The position being decided on, the borders must be prepared, and it all depends on the state of the land as to what should be done, as if wet and heavy the border must be drained. This will entail a fair amount of labour, and should be in no way neglected. If room can be spared the border ought not to be less than 8 feet wide. All the soil should be taken out to about 3 feet deep, and a layer of drainage put in, consisting of clinkers and brickbats, having previously sloped the bottom outwards about an inch to the foot. This, with the aid of a drain under the wall, will answer very well. If, on the other hand, the subsoil is dry and sandy, this will have to be removed and replaced by suitable soil; but should the border contain good soil, a trenching will be all that is required, mixing in a fair amount of lime rubbish and charcoal to keep the border sweet, with an addition of wood ashes.

Having taken the soil out it must be substituted by something better. The best staple is sound turfy loam, but I am afraid expense has to be spared sometimes, so that it would be difficult to lay down a hard and fast rule. I should say, therefore, the soil must approach the loam as near as possible, mixing with it such ingredients as I have previously mentioned; but on no account must animal manure be used, for if the soil is in any way good it will help to produce rank growth, which is difficult to control. The trees can always be helped by top-dressing.

In planting, the trees should be at least 15 feet apart, but give 20 feet if space can be spared. I think it a good plan to afford a fair amount of room, for crowding means hard cutting, which Peaches do not appreciate. It is often the practice when planting fan-trained trees (which are the most popular form) to supplement with standards, as it helps to fill the vacant space until the others get up, when the “riders” are, of course, removed to give place to the permanent ones. The end of October or beginning of November is the best time for planting.

The best trees for planting, in my opinion, are two-year-old from maidens, unless quicker returns are wanted, then of course other trees must be utilised. Care must be taken to plant about 6 inches from the wall, and not deeper than the tree has been previously growing. There is no doubt that with proper planting the trees will start with healthy growth as soon as the spring arrives.

It is not desirable to lay down any rule with regard to training, but the branches must be kept well down on each side to keep the middle open, as if this is not done strong central growths will be produced. It is very well to state a systematic way of training, but more often than not the grower cannot get the buds to break just where he wants them, and so has to shape the tree as best he can; not that I am going to speak against systematic training, for I think it is a great help, especially to beginners. Care should be taken not to overcrowd the trees, for weak and unripened wood is of little use.

Heeling in the young shoots should not be neglected as soon as they are about 6 inches long. It keeps them at the proper angle, and

greatly helps to improve the shape of the tree. Another thing that should be well looked after is the tying in of young shoots, especially in young trees. If tied too tightly the bark is often found cut through, which will cause an ugly wound, or perhaps the loss of a branch. Mulching with some good straw manure will aid the trees in making and keeping surface roots.

I will now name a few sorts for maintaining a successional supply against the wall outdoors. It is impossible to give the exact time a certain sort will ripen, for that depends on the situation, but I will give them as near as I can for the average situation.

Peaches.—Alexandra, Early Beatrice, Waterloo, and Early Rivers for the middle of July; Condor and Hale's Early for the first week in August; Rivers' Early York, Crimson Galande, and Dr. Hogg for the middle of August; Bellegarde, Dymond, and Alexander Noblesse for the first week of September; Royal George second week in September; Princess of Wales latter end of September; Sea Eagle and Golden Eagle for October.

Nectarines.—Early Rivers and Lord Napier for the middle of July; Hardwicke Seedling, Stanwick Elruge, and Rivers' Orange for the month of August; Pineapple and Violette Hâtive for September; and Victoria for October. Those mentioned are no doubt some of the best that can be grown both for outdoor and under glass culture, either in private or market places.

I will now run through the general routine of the work amongst trees in their fruiting stage.

If the tree has been well looked after in the growing season there should not be much pruning required, except the shortening of a few of the long bearing shoots and removing surplus growth. This ought to be done as soon as convenient after the leaves fall. One thing must be well attended to when cutting back—that is, to cut to a wood bud, which, to an experienced eye, is easy to detect, the latter mostly appearing singly or between two flower buds. The wood bud is more pointed than the fruit bud.

After pruning some like to paint the trees; but I am no advocate of this except to eradicate scale. It is an old custom, and some growers think it a mistake to omit it. I have under my care about 200 trees, and some of these have never been painted, and I find on the whole they keep quite as clean as regards insect or disease as those that have been dressed. When the pruning is done tie or nail the shoots neatly back in their places, and lightly point over the surface of the border after having spread on a little chemical manure or wood ashes and some new soil, as these will do much to encourage surface rooting.

The next thing to be considered is the protection of the blossoms from frost and cold winds. Where there is no glass coping this can be done by hanging bunting over the trees at night. If favourable weather prevail a good set is often obtained without much trouble as regards fertilisation; but it is perhaps preferable to brush over the flowers of shy setters, a rabbit's tail tied to a stick being very useful for the purpose. When bees are not plentiful the more prolific bearers should be gently shaken about midday.

The young growths will then require the attention practically called disbudding, which should be done at two or three different times. First of all the back and breast wood must be attended to, and afterwards great care ought to be taken, for this is the stage when the bearing wood for the next season must be chosen. For this I like to reserve a good shoot, as far back into the previous year's wood as possible. This will keep the tree well in hand, and prevent the appearance of long naked branches. When the fruits are set it is advisable to stop all shoots to about four leaves until the fruit-thinning is done, when all that are not wanted may be removed.—(Paper read by MR. S. H. SNELL, Torquay Fruit Farm, at a meeting of the Torquay Gardeners' Society.)

(To be concluded.)

A FACT ABOUT TOMATOES,

Most of us know how thoroughly bad is the practice of planting the majority of plants, trees, and shrubs too deeply. The evil effects of such a practice have been repeatedly pointed out in the horticultural press, and many a man has read such timely warnings soon enough to save his trees from disaster. Exceptions, however, occur to well nigh any established rule. Tomatoes form a notable one among softwooded plants, and it is fortunate that such is the case.

When seed is sown during the autumn, with the object of getting a crop as early as possible, the young plants frequently become weak and leggy; and although all good cultivators like to see their fruit trees and flowers as near to the ground as possible, they hesitate to pot or plant the young plants deeply through fear of failure. I can assure such that they need hesitate no longer. I have tried several experiments in regard to deep potting and planting during the last year, and now make a regular practice of potting deeply, and burying an inch or two of stem at planting time in the case of all plants in the

least leggy. The practice not only insures the envied truss of flowers near the soil, but also gives the plant greater root force, for roots are quickly emitted from the buried stem.

We have just been repotting plants which were potted deeply some weeks ago, and in every instance white fleshy roots had been sent out from the buried portions of the stem. An immense amount of Tomato potting will during the next few weeks be done in various parts of the country, and I invite all interested to test the matter for themselves, and, with the Editor's permission, record their experiences in the *Journal of Horticulture*.—PRACTICE.

POTTING COMPOSTS.

At this season, when a large amount of potting is being daily performed in the majority of establishments, it is well to sometimes think over our cultural practices, and endeavour, if possible, in some way, to improve them. No matter how successful a man may be in plant-growing, there are generally some instances in which the desired results are not obtained. Plants which promised well in one stage of their growth after being potted will occasionally fail to start properly, and even if after a good deal of "nursing" they eventually succeed, "time and labour" are lost in our efforts to put matters right, and few things are more valuable in present days than these commodities.

It is, therefore, obviously of the utmost importance to mix such composts for various plants as our experience has taught us are safe ones to employ. But here another difficulty presents itself—we cannot always obtain the same kind of loam or peat, as they vary considerably in different districts, and a certain amount of experience in each locality is necessary before one can with certainty prepare suitable potting composts. The soils of some districts are so full of eelworms that many plants never succeed in them unless special preparation is given. I have known instances in which good cultivators could never succeed in growing Malmaison until the simple plan of first burning the potting soil was practised, then with the same cultural practices in other respects all went on satisfactorily. How simple a proceeding to employ to convert failure into success; yet I suspect that it is generally by simple means thought of at the right time that most difficulties are overcome.

One cardinal rule to be remembered in preparing composts of all descriptions is to avoid using soil which has the slightest suspicion of sourness. In making this statement I do not condemn the use of old potting soil, as by reason of the decaying humus it contains it is particularly useful in spring time for potting off seedlings or newly rooted plants, but the only safe course to pursue with it is to have a systematic method of preparing it for use. My practice is to have it placed in a heap in the open air for twelve months before use, so that air, heat, and moisture may sweeten and enrich it. The heap ought to be turned at least once, giving a sprinkling of newly slaked lime as the work proceeds. With the addition of a little burnt refuse and sand we then have a compost suitable for all kinds of softwooded plants and seedlings.

Turning to such plants as Fuchsias, Zonal Pelargoniums, and Marguerites, it is common practice now to use a simpler mixture than formerly. Old Tomato soil, decaying turfy loam, or even good garden soil, with the addition of one-fourth of stable manure and a similar quantity of leaf soil, form a regulation compost often used. But as a matter of fact many noted market growers use loam without any addition. This loam is often almost devoid of fibre, and inclined to be heavy, yet the plants, which are potted firmly in it, under good management turn out wonderfully sturdy and floriferous.

Plants potted in materials of this description require comparatively little water until the soil is permeated with roots, and even then water is required less frequently than in the case of plants potted in a lighter soil; indeed judgment in this matter makes all the difference between success and failure, and a practical waterer must always be able to discriminate between plants potted in light soil and others in heavy. The good results obtained by the use of such simple composts are largely brought about by the aid of chemical manures, as without them I make bold to assert the cultural feats now accomplished would be impossible. When once the roots of plants begin to work in new soil periodical dressings of the best of these manures seem to give the plants a wonderfully increased power of root production.

The food contained in these manures being in such a condition as plants can at once assimilate, enables them to penetrate it in a few days, whereas in the case of natural manures decay must begin before the roots can obtain food, and then only a limited amount is given up at a time. This perhaps accounts for the remarkable results to be obtained by the use of chemical manures for pot plants. From the foregoing remarks I think we may deduce the sound fact that in the culture of softwooded plants in small pots the vital point to aim at in preparing composts is to use only soils which are sweet, and rely upon chemical manures to do the rest.—H. D.

ASPARAGUS NOTES.

Mr. Shalford (page 60) says, it is difficult to write anything new bearing on Asparagus culture, and this is no doubt true. The same, however, may be just as correctly said of other vegetables; but this is no reason for apology on Mr. Shalford's part, because the routine of so variable a character, yet so clearly given, must be helpful to the younger gardeners, so many of whom are readers of the *Journal of Horticulture*. It is to young men who have just taken upon themselves the responsibility in the position of gardener, head or otherwise, that hints in vegetable growing are helpful.

There is no uniformity of result, or any one particular rule governing the cultivation of Asparagus, but individual gardens require treatment according to the nature of the soil and position, and there is a wonderful and varying influence brought to bear upon this vegetable from the character of the land alone. In light sandy soils with plenty of manure it will, as Mr. Shalford says, grow like a weed; in heavy and strong land it is just the reverse, except special provision is made for planting.

I well remember Mr. Iggulden, when at Marston, found a difficulty in establishing satisfactory plantations until he made a special effort to obtain the materials for raising the beds to the level of the natural soil, a good depth of drainage being the first provision. Although on a large scale it is a laborious undertaking, it is work that is well repaid in after years, especially in cases where they are intended for use over a long series of years. At Marston the soil is of a very heavy nature, the subsoil being stiff clay. Planted in the natural surface soil, the roots perished to a serious extent in winter, and frequent purchases had to be made for replacing losses which occurred. The soil here is neither so wet nor heavy as at Marston, but some portions of this garden are totally unfitted for Asparagus, given ordinary attention. Roots and crowns decay to a serious degree, which means thin beds and poor crops; in fact, the ground is simply wasted in attempting to grow it under the usual easy methods.

Another aspect not mentioned by Mr. Shalford, but which is a very prominent one, is presented in the late date on which cutting commences on heavy ground. It becomes disappointing to a degree when your neighbour, perhaps no great distance away, begins cutting heads in fair abundance several days in advance of yourself; and Asparagus is a vegetable perhaps, more than any other, in which the first dish is anxiously anticipated. Heavy dressings of manure put on in winter and left until the spring months have well advanced are fatal to early cutting. Personally I have no sympathy with thick coatings of farm manure to be again removed in spring, nor with the cutting of deep alleys between the beds, shearing off the roots and exposing the mutilated parts to the action of wintry weather. Short manure, either in a decayed or fresh state, and this allowed to remain, seems to me more beneficial to the beds and very materially reduces the attendant labour, and this is a consideration that few can afford to lightly set aside.

The planting season does not occur until April, but in the interval there is time to prepare new beds. From now onwards there will be much refuse about the garden to be cleared away, and the preparation for Asparagus beds affords an easy means of dealing with what would otherwise be a laborious undertaking in a large garden. Throw out the soil the width and length intended to a depth of a foot or 15 inches—more if the operator wish. This will take a considerable amount of refuse to fill; then a good layer of manure, decayed or fresh, spread over this, and the soil replaced, the bed will be elevated above the surrounding surface. The refuse and manure beneath will sustain the plants for a long time, and their productiveness will increase as the roots take possession of such a good store of decaying matter. The tenacious Asparagus is to burrow deeply, and this explains pretty clearly why plants collapse in heavy soil not well prepared. In deeply excavated trenches tree prunings may be made to serve as drainage very effectively.

I agree with Mr. Shalford, that salt sometimes is too freely used; in light soil its injurious effects may not be so clearly seen, but on heavy land it makes the surface pasty and cold. It is a better practice to give a lighter dressing twice, or even three times during the summer. Salt used for bacon-curing purposes has not much value in it, although it is often purchased by growers in the district where bacon "factories" are located. I have tried it, and noticed that the weeds simply revelled in it; and salt that has not sufficient property left in it to hinder, if not actually destroy weeds, must prove an unprofitable investment. A smaller quantity of a good article must be an all-round advantage.

In dealing with the permanent planting of Asparagus it is most important that the ground be quite clear of perennial weeds, such as knotted or plain rooted Couch Grass and Bindweed, for if these once get established among Asparagus roots neither salt nor other antidotes will exterminate them. The only course open is to destroy the beds and replant others in fresh ground. Under the best conditions there seems, so far as I can ascertain, no limit to the age in which

Asparagus will remain productive. I know of beds at the present time that have existed over sixty years, and are still as healthy and vigorous as ever. With generous treatment it would be impossible to predict a time when they would cease to produce their annual crop. These are raised beds overlying a heavy clay subsoil, and their position not so favourable as to give the plants the prospect of such a long and useful career.—W. S., *Wills*.

FUCHSIA CULTURE

THE best period of the year has arrived for commencing the spring culture of old-established Fuchsia plants. Medium-sized and large specimens do good service during the summer months in brightening the conservatory and greenhouse with their richly coloured pendent blooms. The Fuchsia is not the best of plants for affording cut blooms of the most useful character, yet the flowers may be cut and employed for some purposes. The true character of the Fuchsia is as a decorative plant, whether it is grown in pots or planted out.

Plants may be grown in various ways. Standards with a head of growth on the summit of a single stem are extremely useful in a collection to stand above dwarfier plants. Trained in pyramid form, well flowered examples are certainly attractive. They are not difficult to produce in this manner either from seed or cuttings. Less informal plants also may prove useful, and if healthy and free growing they will at the proper time bloom freely. Plants grown in tubs or pots and trained on wires under the roof can be established permanently, and allowed to cover as much space as convenient with several principal branches, on which spurs may be formed, and these have the long growths which issue from them shortened to a few buds each year.

Fine plants can soon be established if planting cut in a border be adopted, so that the roots will have a free run in good soil. Long, strong growths are quickly produced, and these ought to be laid in at equal distances to cover the space it is desirable to furnish. It may not be possible to carry it out in one season, but it can eventually be done.

Plants in pots which have been wintering in a cool frost-proof structure, and kept moderately dry at the roots, may now be brought out, and the growths pruned back. Old plants which have their shape fully formed should receive close pruning, shortening the shoots to a few buds. Those that are less informally trained and young plants need not be so closely pruned, reducing the length of strong young shoots one or two-thirds, and weak spray closely or cut out completely. The main thing in pruning Fuchsias is to cut out all unripe wood. So long as this is done, and no particular shape of plant is desired, they will succeed. The permanent plants in pots and borders require similar pruning, but as a rule must be fairly closely reduced. After pruning give the roots little water until new growth commences, then afford more.

At this time with pot plants it is found the best period to shake out the plants from the old soil, trim the roots slightly, and repot in fresh soil and clean pots of the same size. The compost employed should be sweet and rich, formed principally of turfy loam, leaf soil, old manure, and sand. The proportions may be loam four parts, leaf soil two parts, old hotbed manure or well decayed cow manure one part, with a good sprinkling of sand. Pot firmly, but not hard.

It will be an advantage if the plants can be stood in a warm house and daily syringed. The soil being moist when potting little water will be required at the roots until they are working freely in the new compost. Permanent plants in borders, large pots, or tubs cannot be so easily dealt with at the roots, nor do they require it so much, but they may at least have some of the old soil taken away from the surface down to the roots, and a layer of fresh material added. Into this a network of young fibres will ramify, and benefit the growth and flowering to a large extent. These Fuchsias scarcely need so much syringing of the early growth as those in pots, but when well advanced an occasional thorough wetting cannot but be of service previous to the growth becoming heavy and commencing to flower.

Pot plants making good growth will probably require additional root room. This must be decided by the number of roots and their activity. Give a free and liberal shift if it is found necessary to afford more room.

Young rooted plants in cutting pots, or established singly in small-sized pots, may be potted in the compost recommended for older plants. They can be simply grown to one principal stem and lateral growths encouraged to form, or be pinched in order to form several growths. Standards are formed by taking up a principal stem to the height required, then pinch out the top and encourage several growths to extend, which also may be topped when long enough, so as to increase the number.

Spring is a suitable time to propagate Fuchsias. Strong young growths starting from old stems form very suitable cuttings. Insert in sandy soil singly in thumb pots or round the edges of 3-inch pots, placing in a propagating frame, or under a hand-glass in a warm moist house, until rooted. Divide, and pot singly, growing them for any purpose desired.—E. D. S.

CYMBIDIUM HOOKERIANUM (GRANDIFLORUM).

LARGE numbers of Cymbidiums are grown in various places throughout the country, and with reasonably good care and attention seldom fail to give complete satisfaction to their owners. Handsome plants of Cymbidium Lowianum have a most telling effect in rockeries in houses of suitable temperature, such as that at Clare Lawn, East Sheen, the residence of Sir Frederic Wigan, Bart. There, as so excellently grown by Mr. W. H. Young, they are superb, and receive the unstinted praise of every visitor. The species *C. Hookerianum* is a most attractive one. Williams' "Orchid Manual" says it is, "similar in its habit of growth to *C. giganteum*, with tough leathery strap-shaped distichous leaves 2 feet long, striped with yellow along their sheathing base. The scape is radical, erect, nodding in the upper floriferous part. The individual blossoms (fig. 22) are very large, 4 to 5 inches in diameter, the sepals and petals yellowish green, and the lip straw coloured, deeper yellow at the margins, near which, on the crispy ciliate front lobe, are large blotches of rich crimson purple, while the flat-fringed acute-angled side lobes are covered with smaller crimson dots; a pair of velvety crimson spotted lamellæ occupy the disc." It is a native of the Sikkim mountains, and should be grown in the *Cattleya* house. This will probably meet "Orchid Grower's" requirements.

CHARCOAL FOR ORCHIDS.

MUCH has been written respecting the benefits to be derived from the use of charcoal in the different composts for Orchids. I should much like to know if it is really necessary to their well-being. For some years past I have discarded it, and as yet I cannot see any ill effects. I still think if we treated Orchids more rationally, and did not do so much coddling, we should not hear of so many failures.—J. T. B., *Hessle*.

[Charcoal is not absolutely necessary to the well-being of Orchids, as "J. T. B." has proved by growing plants without it for "some years." It is, nevertheless, one of the most useful aids to culture, and it would be interesting to know why your correspondent has discontinued using it. Charcoal cannot possibly do any harm if it is of the right quality, and has been several times slightly damped before use. It is lighter than crocks, and therefore more suitable for mixing with the compost. It takes up moisture easily, and gives it off again to the root spongioles, while the roots show their liking to it by clinging to it firmly. When repotting plants out of order, we have often found the only healthy roots to be those that had by chance found a bit of charcoal.]

As to the coddling, this has nothing to do with the question; the charcoal is used as a means of assisting the compost, for if nothing but moss and peat be used, this would get very sour and close, while, as mentioned, the charcoal is lighter than the crocks sometimes used for the purpose. Different kinds of volcanic substance, such as tufa, are often used in place of either, and very good results have been obtained. These are not, however, always easy to get at, while charcoal is to be obtained at a very cheap rate, or it may be prepared at home. Thus, unless "J. T. B." can give a specific reason for not using it, most Orchid growers will still probably go on in the old way, and really some very good plants have ere now been grown by its aid.]

PHALLENOPSIS SANDERIANA.

This must certainly be regarded as one of the finest Moth Orchids in cultivation. The foliage is like that of *P. Schilleriana*, but not so distinctly tessellated; the flowers occur on fine racemes, about half a dozen on each, though plenty of instances could no doubt be given of larger numbers. Each flower is about 3 inches across, the colour varying from a pretty soft rose to pure white. It is a good grower, and thrives well in abundance of heat and moisture in company with *P. Schilleriana* and other well known kinds. Its habitat is in Mindanao, and probably other islands of the Philippine group, and has been found growing in close proximity to the lovely *Vanda Sanderiana*. It was discovered by one of Messrs. Sanders' collectors about 1882.

SACCOLABIUM HENDERSONIANUM.

The pretty erect racemes of flowers produced by this species make it worthy a place in every collection. The habit is dwarf, and the flowers are a bright rosy red with a pale lip. The East Indian house is the most suitable place for its growth, and, like others in the genus, it delights in ample sunlight, so that the plants may be brought right up to the glass, and only shaded when it becomes absolutely necessary to prevent injury to the foliage. This treatment, with a brisk moist heat, will cause the growth to be very free, yet hard and floriferous.

It is the foliage grown in dark, shady, overheated houses, with too little air, that is apt to fail at a critical time, such as during a long spell of damp, wintry and dull weather, the lower leaves falling and giving the plants a most unhappy appearance. *S. Hendersonianum* does not require a very large or wide pot or basket, but at the same time there must be sufficient compost to hold moisture, as when growing freely it likes ample. The compost may consist of clean sphagnum moss and charcoal only, above good drainage. During the resting season, that is when the points of the roots closed over give only moisture enough to keep foliage and roots plump. *S. Hendersonianum* is a native of Borneo, and is always found in moist positions, often overhanging streams.—H. R. R.

FIG. 22.—CYMBIDIUM HOOKERIANUM (GRANDIFLORUM).

FOOD OF PLANTS.

THE remarks of your correspondent, Mr. D. Thomson, in the latter part of his article on page 78 of the Journal, are much in harmony with the practice that was followed in the gardens where I held a subordinate position some years ago, and although the atmospheric feeding of plants was done in a different way from that described, I think it amounted to practically the same thing. Instead of fermenting beds of leaves and manure, a tank which received the sewage from the house, outhouses, and other outbuildings, was the agency which supplied the atmosphere of the houses with food and moisture. The water from the tank was carted to a convenient place near the garden and used for damping-down purposes instead of clear water; this was done three times daily, sometimes more, according to the weather.

Orchids, stove plants, Melons, Cucumbers, and Vines responded to the treatment by making luxuriant, healthy growth. It seemed quite wholesome to oneself after getting used to it, and even the ladies offered no objection. I have looked for the sewage in two or three places where I have practiced since; but, alas! it is drained away instead of emptying into a tank, whence it might be used with advantage in the garden. In my present place it empties into the lake, and I get a sniff of it sometimes in the summer, that reminds me of the atmosphere of the houses of which I have spoken. In writing this note I do so in response to the last paragraph of Mr. Thomson's article, not as a teacher or a scientist, but as a labourer suggesting a better method of feeding through the atmosphere.—R. M.

WEATHER IN LONDON.—On each morning of the latter half of the past week there has been a sharp frost. On Friday and Saturday they were rather severe, reaching 12° on the former day; but during the evening of Saturday there came a change to milder conditions, and for some hours on Sunday morning rain fell steadily. Afterwards, and continuing until midday Monday, it was dry, and a light though cold wind prevailed. After this time rain fell heavily until night and again on Tuesday, though there were occasional gleams of sunshine. Wednesday was very wet.

— WEATHER IN THE NORTH.—Although not so severe as in the preceding week, the frost has been continuous up to the 6th, and has ranged from 4° to 12° . Occasionally there has been some appearance of a thaw, but this has not been confirmed. On Monday there was a pretty general fall of snow, but in the evening there was a renewed indication of milder weather.—B. D., *S. Perthshire*.

— ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Royal Horticultural Society will take place in the Drill Hall, Westminster, on Tuesday, February 14th. The various Committees will assemble at noon as usual, and at three o'clock the annual general meeting of the Society will be held at the Society's Offices, 117, Victoria Street, Westminster, S.W.

— DEATH OF MR. FOLLOWS.—We learn with regret of the recent demise of Mr. Follows, for many years accountant to the firm of Follows and Bate, Ltd., engineers, Manchester. He was brother to Mr. F. W. Follows, the present head of the firm. The deceased was a great lover of wild flowers and birds, and spent much time amongst them. He was a member of the Society of Friends.

— SINGLE-HANDED GARDENERS.—My good friend Mr. Thornton seems rather troubled as to the shaping of a proper definition for this section of gardeners. It is easier to make suggestions of a general nature than it is to satisfy the needs of every case. Really gardeners' circumstances vary so much that very often cases can be dealt with only on their merits by exhibition executives. For general purposes it may be sufficient to describe a single-handed gardener as one "who has no constant assistance," or as one "who has only occasional assistance," or as one "who has no assistance whatever." But the latter describes a line that is too hard and fast, and either of the others seem to meet the general needs of the case, though they may not every individual case. But even at so popular a show as is that at Beckenham the class does not include so many competitors, but each one's circumstances are pretty well known, and then placed into that category which most nearly fits him.—A. DEAN.

— DEVON FINGER-AND-TOE EXPERIMENTS.—Experiments were conducted last season at Corringdon Farm, South Brent, for the purpose of testing the value of ground lime as a cure for "finger-and-toe" in Turnips. It was thought that a small quantity of ground quicklime, thoroughly incorporated with the soil, would do much to prevent this scourge, if not cure it altogether. The field chosen for the trial had a bad reputation for finger-and-toe, and half an acre of this was divided into five plots. The whole of the half acre was dressed with quicklime at the rate of a ton to the acre some three months before the sowing of the crop, and another dressing at the same rate was applied five weeks before the crop was put in. The five plots into which the half acre was divided were each dressed with different manures. The plot which gave the best yield, says a contemporary, was that dressed with basic slag alone, applied in April, while that dressed with slag and superphosphate mixed and applied at the time of sowing gave just over a ton less, the plot dressed with superphosphate alone coming next, while basic slag and bonemeal followed, but farmyard manure alone gave less than half of any of the others. It must be remembered, however, that manure on an infected farm is one of the surest means of retaining the fungus. These experiments, as a whole, when compared with the rest of the field, show that lime had had a very beneficial effect, and, though no part of the field was free from infection, there were far less traces of it in the limed plots, and a difference of 4 or 5 tons in the weight of the crop was noticeable. Some of the unlimed parts produced very little crop at all.

— GARDENING APPOINTMENTS.—Mr. S. Barker, for the last six years foreman in the Lord Burton's garden at Rangemore, Burton-on-Trent, has been appointed head gardener to his Grace the Duke of Newcastle, Clumber, Notts. Mr. A. Shilton, late of the Rangemore Gardens, has been appointed head gardener to the Hon. Mrs. Bass, Needwood, near Burton-on-Trent.

— MR. GEO. WYTHES, V.M.H.—We are informed that subsequent upon the death of the late Duke of Northumberland some changes are being effected at Alnwick Castle. Mr. G. Harris, who has had charge of the gardens for some years, is about to commence business in Alnwick, and Mr. Geo. Wythes, of Syon House, will hereafter have the northern estate added to his charge. It is a large undertaking, but Mr. Wythes is a strong man and will doubtless prove himself equal to it.

— GRAND YORKSHIRE GALA.—The schedule of the Floral Fête which is to be held in the Bootham Field, York, on June 14th, 15th, and 16th of the current year, has just reached us from the Secretary, Mr. C. W. Simmons. As usual, the number of classes approaches 100, of which several are new. Those that have been in before are still credited with generous prizes, as indeed are the ones that have been freshly incorporated. These comprise classes for "a group of Rhododendrons; a group of Gloxinias; a gold medal for the best exhibit of floral designs; a table of Orchids; an ornamental stand of flowers and foliage, and others." The comparatively few rules are simple and clear. All information can be obtained from Mr. C. Simmons, Harker's Hotel, York.

— NEW F.R.H.S.'s.—At the meeting at the Drill Hall on January 31st no less than seventy-three new Fellows of the R.H.S. were proposed for nomination. As there were nearly as many proposed, and of course elected, at the previous January meeting, that represents for the first month of the year alone some 140—surely a record nomination for January in any year. Better evidence of the high position the Society holds, and its great popularity, could not well be furnished. None the less, it is strange that its operation seems to excite so little interest in Royal circles. That seems inexplicable, and needs explanation. The experiment of holding two meetings in so dead a winter month as is January, apparently not justified at the first gathering, was amply so at the recent meeting, when quite a pretty and interesting show was furnished. No doubt for the rest of the year we shall see the displays increase in bulk and interest.—D.

— WOODBRIDGE HORTICULTURAL SOCIETY.—The annual meeting of the subscribers and others interested in the Horticultural Society was held on Friday last, Capt. R. J. Carthew presiding. The financial statement for the past year was presented by the Hon. Secretary, Mr. John Andrews, and showed a total income of £374 13s. 7d., and expenditure of £374 10s. 2d., leaving a balance in hand of 3s. 5d. On the proposition of Mr. John Loder, seconded by Mr. Alfred Gall, a hearty vote of thanks was given to Capt. R. J. Carthew for granting his beautiful grounds for the site of the show. A similar vote was accorded to the Hon. Secretary, Mr. John Andrews, whose services and zeal for the success of the Society cannot be too highly extolled. Col. Salmon, Mr. T. G. Heatley, Mr. S. T. Pulham, and Mr. J. Easton were elected to fill vacancies on the Committee. Thursday, July 13th, was fixed as the date of the show for this year.

— ISLE OF WIGHT.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday last. Dr. J. Groves presided over a good attendance of members. Mr. Geo. Bennett, Ryde, gave an interesting lecture on the "Cultivation of Potatoes." The lecturer deprecated the practice of planting sets with shoots on, as his experience convinced him they did much better when planted without shoots; he also strongly recommended early and deep planting, a depth of about 9 inches he should advise as being the most suitable. Flat hoeing he considered most beneficial, but earthing of Potatoes he thought quite unnecessary. The subsequent discussion was taken part in by a large number of those present, who detailed their experiences in Potato culture. A vote of thanks was accorded the lecturer on the proposition of the Chairman, seconded by Mr. J. O. Brook, and supported by Mr. T. Gibbs. The exhibits staged consisted of clean and well grown plants of *Solanum capsicastrum* and *Camellia* blooms exhibited by Mr. W. Morris, gardener to Captain Eveleigh, Newport, and some fine Primulas from Mr. W. E. Wickens, gardener to R. R. Pittis, Esq., Tugley House, Newport. The exhibitors each received the Association certificate for cultural merit. A mid-monthly meeting of the Association will take place at Whitwell on the 18th inst., when a lecture will be given on "Bees and Bee-keeping."—S. H.

— **SUSSEX WEATHER.**—The total rainfall at Stonehurst, Ardingley, for January, was 3.34 inches, being 1.21 inch above the average. The heaviest fall, 0.53 inch, on the 15th. Rain fell on eighteen days. The maximum temperature was 52° on the 12th and 18th, the minimum 28° on the 26th. Mean maximum 45.19°, mean minimum 36.22°, mean temperature 40.70°, which is 4.21° above the average. Since the 24th the wind has been N.E., with a cooler and dryer atmosphere, giving us several days of bright sunshine, with slight frosts.—R. I.

— **JANUARY WEATHER AT HODSOCK PRIORY.**—Mean temperature, 39.8°. Maximum in the screen, 56.2° on the 21st; minimum in the screen, 18.8 on the 26th. Minimum on the grass, 12.3° on the 26th. No. of frosts, in the shade, 10; on the grass, 24. Sunshine, 33 hours, or 14 per cent. of the possible duration. Rainfall, 1.90 inch; difference from average 0.10 inch. Rain fell on twenty-two days. Maximum fall, 0.34 inch on the 15th. Another mild month with very little frost. Stormy, but no heavy falls of rain.—J. MALLENDER, *Workshop*.

— **THE WEATHER LAST MONTH.**—The prevailing direction of the wind was south on twenty-one days. The total rainfall was 2.70 inches; this fell on twenty-two days, and is 0.92 inch above the average for the month. The greatest daily fall was 0.53 inch on the 21st. Barometer (corrected and reduced), highest reading 30.761 inches on the 26th, at 9 A.M.; lowest reading 28.851 inches on the 2nd, at 9 A.M. Thermometers: Highest in the shade 56°, on the 21st; lowest 20°, on the 25th; mean of daily maxima 45.87°; mean of daily minima 34.12°; mean temperature of the month 39.99°; lowest on the grass 15°, on the 25th; highest in the sun 88°, on the 26th; mean temperature of the earth 3 feet deep, 41.48°. Total sunshine, 67 hours 35 minutes. There were eight sunless days.—W. H. DIVERS, *Belvoir Castle Gardens, Grantham*.

— **JANUARY WEATHER AT DOWLAIS.**—Rainfall, 9.81 inches, which fell on twenty-two days; greatest fall, 2.43 inches, on the 20th. Temperature, mean maximum, 41.548°. Highest reading, 46°, on the 5th; mean minimum, 29.870°. Lowest reading, 16°, on the 25th (being 1° lower than at any time last year). Below freezing point on twenty days, with seventeen sunless days. The wind was in the S. and S.W. on fourteen days, and in the E. and N.E. on eleven days. On the 1st of the month we had hail, rain, snow, thunder, and lightning; a heavy storm on the 16th, rain, hail, thunder and lightning. A terribly stormy month, the wind on several occasions was terrific, especially from the 20th to the 22nd inclusive. Since then it has been quiet with very sharp frosts. From December 25th to January 22nd 14.69 inches of rain fell, the greatest daily fall being 2.82 on December 26th.—WM. MABBOTT.

— **TRAPPING BULLFINCHES.**—Excellent advice "Avis," on page 83, and if you had added 2 to 4 ozs. of softsoap to the gallon, and recommended also applying the mixture as hot as the finger can be borne in it, you would have repeated what I have advised hundreds to use, both to deter birds taking the buds and to kill insect pests, such as aphides and red spider. I found these hatched out a fortnight ago, and how they will stand the frosts I shall be anxious to see. My advice *re* bullfinches is an alternative to the gun and the damage to fruit trees, their general fate; and as people will have cage birds, why not the most destructive bird we have, remembering that they will take clean out and prevent any future growth, twenty to twenty-five Green Gage buds in a minute? Although sixty-two have so far placed themselves in cages in my garden this winter, there will be a plentiful stock left for breeding, for I heard of thirty being driven from our nearest fruit plantation yesterday, and the woods are alive with them.—J. HAM, *Astwood Bank, Redditch*.

— **PROTECTING ORCHARDS FROM LIGHT FROSTS.**—It was, we believe, William Saunders, the chief of the Government Experiment Gardens at Washington, who, some fifty years ago, insisted that the text books were wrong in teaching that heated air ascended—that is, ascended in an active sense. It was, rather, pushed up by the heavier cold air pressing against it. It seems a slight distinction, but it has immense practical importance. For instance, those who understand this smile at the Florida Orange grower, who builds fires around his orchard to make smoke when he fears a frost is coming. He lightens the atmosphere at the same time among the trees, and makes it all the easier for the heavy cold air to push in and take its place. The modern thought to spray with water is more philosophical. Water is a good conductor of heat, and would add to the chances of resisting cold by the heat it would abstract from its surroundings. Horticulturists have long known that evergreens are quite hardy in a moist atmosphere, when they would easily succumb under the same temperature in a dry one.—("Meehan's Monthly.")

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, to be held, by kind permission of the Council, at Great George Street, Westminster, on Wednesday the 15th inst., at 7.30 P.M., the following papers will be read:—"Report on the Phenological Observations for 1898," by Edward Mawley, F.R.Met.Soc., F.R.I.S. "The Circulation of the Atmosphere," by Prof. W. M. Davis, M.A.

— **CLEMATIS INDIVISA.**—There are few more charming members of the Clematis family than the variety mentioned above, and perhaps there are none more useful. The pillars and walls of a cool conservatory or corridor suit it admirably, as the plant is not quite hardy enough for outdoor culture. It is robust in habit, quickly covering the space allotted to it, and its stout green foliage possesses the characteristic of keeping remarkably clean. The graceful white flowers are produced in great profusion in the spring, and are useful for many forms of decoration. The flowers are borne in clusters, and will last some time in a cut state if gathered young. Being light and elegant they are well suited for the make-up of wreaths, crosses, and bouquets, as well as for table and other decorations. Given a free space for rambling and a fair rooting medium Clematis indivisa is one of the most charming of climbing plants for a cool house.—H.

— **A PLEASING COMBINATION.**—There is now no lack of White Roman Hyacinths for decorative purposes, and there is no need to enlarge upon the sweetness and elegance of these chaste flowers. Another well known and popular plant is now also in bloom, *Cypripedium insigne*, than which there is no more useful and accommodating member of the Slipper Orchid family. The blooms of this Orchid, used in conjunction with White Roman Hyacinths, make a most happy blend for table and room decoration. The flowers of the former, of course, last double the time of those of the latter, but when the Hyacinths are beginning to show signs of failing they may be removed, fresh water given, and others put in their place. As a decorative flower *Cypripedium insigne* is unique on account of its elegant habit and the long time over which it will keep in good condition after being cut. The two flowers mentioned and tips of scarlet Poinsettias make a pleasing decoration for a dinner table.—G.

— **BROWNEA CRAWFORDI.**—One of the most striking plants at present in flower at Kew is the subject of this note. It is planted out in a bed of loam in the Palm house, where it has formed a large spreading bush 15 feet high, with pinnate leaves 2 feet long. Altogether there are upwards of twenty heads of flowers open now, and a fine display is made. The flowers are bright red, with orange coloured anthers. They are borne in dense globular heads, 7 to 8 inches across and 4 inches deep. The stamens protrude an inch or more from the mouth of the corolla, and twist about in such a manner as to resemble a tangled mass of red thread, with orange-coloured spots here and there. It is a hybrid, raised by the man after whom it is named, between *B. grandiceps* and *B. macrophylla*, and is an improvement on both. It can be flowered well in pots, but does much better under the more generous system of planting out. In addition to the beauty of its flowers, the foliage when young is lovely, the young leaves as they develop being mottled with beautiful shades of green and brown. Anyone with room in a large stove will do well to give this plant a trial.—KEWITE.

— **SALIX BABYLONICA NAPOLEONA.**—In the comprehensive list of Willows, described by Mons. Rebder in the "Deutsche Gartner-Zeitung," the variety known as Napoleon's Weeping Willow does not appear. I do not know if it is common in any part of the kingdom, but it will be interesting to know that there is an old and flourishing specimen growing within a few minutes' walk from where I am writing. Its history appears to be comparatively little known in this neighbourhood. Tradition, however, declares that it is a scion obtained indirectly from the celebrated Willow growing over Napoleon's tomb at St. Helena having been given to the late John Cox, Birmingham's celebrated landscape painter, by Napoleon III. from a specimen growing in the gardens of the Palace of the Luxembourg in Paris, when the artist was being conducted over the gardens by the late Emperor. His Majesty requested Cox to take anything from the gardens as a memento of his visit to Paris, and naturally he selected a cutting from a specimen Weeping Willow pointed out by the Emperor as a descendant of the original or St Helena tree, and this was placed in the grounds of Greenfield House, the residence of the artist. It is now growing by the side of one of the substantial brick-built and stone-capped carriage entrance gate pillars, and its graceful boughs depend both over the gateway and a portion of the public road. The tree appears to have attained the normal height of the variety, about 16 feet, according to "Johnson's Gardeners' Dictionary."—W. G.

— **AMATEUR WORLD OF HORTICULTURE.**—This is the official organ of the National Amateur Gardeners' Association, and the Secretary has just favoured us with the last quarterly number. It contains much of general interest, such as the papers of Plant Breeding, Hardy Fruit, and Intermediate Orchids, but naturally the major portion of the contents appeal most directly to members of the Association.

— **ARE NURSERYMEN'S ASSISTANTS DOMESTIC SERVANTS?**—A case of enormous importance to nurserymen and landscape gardeners has been decided at Manchester. Mr. James Treeby, nurseryman, sent a man to work in the garden of Mr. Estcourt, this gentleman paying Mr. Treeby for the man's services. The Revenue authorities claimed that Mr. Treeby should pay a license for this man as working in a private garden. The Stipendiary Magistrate agreed, and inflicted a fine of 5s. and costs. Leave was granted to state a case for appeal, and it can hardly be expected that nurserymen will acquiesce in a change from an universal custom that has been in operation for generations, if not for centuries. It will be a serious matter for many, if not most nurserymen, if the present decision stands, and the law as determined by the Magistrate generally enforced.

— **SINDACATO AGRICOLO DI TORINO.**—We are requested to state that an International Competition for Seed-sowing and Manure-spreading Machines, promoted by the Agricultural Syndicate, will be held in Turin from the 1st of March to the 30th of November, 1899. The awards will be—for seed-sowing machines: a, a gold medal, 250 francs in cash, and the acquisition, by the Board of Agriculture, of the machine winning this prize; b, a silver medal and 150 francs in cash; c, a silver medal and 100 francs in cash; and d, a bronze medal. For manure-spreading machines: a, a gold medal, 150 francs in cash, and the acquisition, by the Board of Agriculture, of the machine winning this prize; b, a silver medal and 100 francs in cash; c, a silver medal and 50 francs in cash; and d, a bronze medal. Demands for admission, which must be made not later than February 15th, 1899, and for further information, must be made to "Comitato Ordinatore," care of "Sindacato Agricolo," 49, Via Carlo Alberto, Torino, Italy.

— **ERYTHROCHITON HYPOPHYLLANTHUS.**—An example of this interesting plant is now in flower in the Palm house at Kew. It is about 15 feet in height, with a small branched head of dark green, leathery leaves 18 inches long. When out of flower it is a very ordinary looking plant, but when in flower the manner in which the flowers are produced makes it of great interest. These are borne usually two or three together from the under side of the midrib of the leaf, sometimes from near the base, and sometimes half-way along. They are pure white, and $1\frac{1}{2}$ inch across. Occasionally a secondary leaf attends the flowers. It was figured in the "Botanical Magazine," t. 5824 in 1870, and from the description given with it, it was flowered at Kew first in 1864, the plant being sent to Kew by M. Linden of Brussels, who introduced it from the province of Ocaia in New Grenada, where it was found growing in rocky ravines at an altitude of 2500 feet. A second species, *E. brasiliensis*, is in cultivation: this is the showier of the two, the flowers being borne in racemes a foot or more long. A figure and description of this may be seen in the "Botanical Magazine," t. 4742.—D.

— **COMMONS PRESERVATION SOCIETY.**—At a meeting of the Executive Committee it was reported that of the "private Bills to be introduced into Parliament in the coming session forty-seven come within the purview of the Society. The aggregate area of common lands affected is more than 1934 acres, while various Bills propose to take power to extinguish numerous public rights of way. Included amongst the Bills to which exception was taken by the Society, and which it was resolved to oppose unless suitable concessions are made in the public interest, is that by which power is sought to acquire 17 acres of Tottenham Marshes, and portions of Leyton, Walthamstow, and Cheshunt Marshes, and to acquire 2 acres of Earlswood Common, Redhill, a common which is the subject of a regulation scheme under the Commons Act, 1876. A special report was ordered to be made upon the Bill promoted by the East London Water Company, which proposes to absorb for new reservoirs no fewer than 194 acres of Lammas land in the parishes of Chingford and Waltham Cross. It was resolved to oppose the Bradford Tramways and Improvement Bill, by which the Corporation of Bradford seek to acquire the whole of the common lands of the Manor of Baildon, comprising altogether 770 acres of open space. Of this area the Corporation propose to sell 50 acres to provide money to meet the expenses of acquiring the land, while the lord of the manor will be compensated for his interests by the payment of a sum of £7000 and by the conveyance of a further 50 acres of the commons.

— **NATIONAL AMATEUR GARDENERS' ASSOCIATION (LIVERPOOL BRANCH).**—A very successful annual meeting was held recently, Mr. J. H. Drake presiding. The Secretary, Mr. J. M. Smyth, read a capital report of the progress during the past year, which, after paying much larger sums as prizes, had a balance in hand of £5. The following sums were promised in the room—viz, A. L. Jones, Esq., and W. J. Davey, Esq., two patrons, 2 guineas each; Mr. Histed 1 guinea; and Mrs. Langley, for Essay, with Messrs. Hoskyn, Rowlands, Cangle, Butcher, and Drake, half a guinea each. The silver medal for highest number of points was won for the third time by Mr. A. Cooper, and the bronze medal by Mr. Cangle, the latter also winning the silver medal and certificate presented by Messrs. Toogood and Sons. The most successful exhibitors of the season were Messrs. Cangle and Lunt. Mr. Histed was unanimously elected President, and he promised to help the Society both in the matter of new members and also to the prize fund. Mr. Drake was heartily thanked for his conduct in the chair during the past year, a statement being made that, notwithstanding his pressing business affairs, he had been present at every meeting, and he was elected as Vice-President. Messrs. Smyth and Cooper were elected Hon. Secretaries, Mr. D. W. Cangle Exhibition Secretary, and Mr. Robins Hon. Treasurer. A hearty vote of thanks to the officers terminated the proceedings.—R. P. R.

LILIUMS AND THEIR TREATMENT.

At the recent fortnightly meeting of the Exeter and District Gardeners' Association at the Guildhall, Exeter, Mr. James Mayne, gardener to the Hon. Mark Rolle at Bicton, read a paper on "Liliums and Their Treatment." As yet, so far as he had been able to ascertain, no writer had told them by whom the Lily was introduced into Britain. Probably they were indebted to the Romans for that noble flower, as well as for many other good things in their gardens. With a proper supply of bulbs it was quite possible to have Liliums more or less in flower throughout the year, especially *Lilium longiflorum* and its varieties. Very few plants could compare with Liliums in the open garden on account of their variety of colour and fragrance, and all were more or less hardy.

Dealing first with those usually given pot culture, and giving the *longiflorum* and its varieties precedence, he advised that they should be procured as early as possible in the autumn, and potted without delay, as all the Lily tribe was more or less injured if allowed to get dry. When the shoots appeared the pots should be brought to the light without delay, and they should be kept as near the glass as possible right up to the time of flowering. If kept under glass during that period a sharp look out must be kept, as green fly was the greatest enemy of this Lily. The plants should be taken into the greenhouse as soon as the flower buds were seen, and there ought to be as little fire heat, or anything in the shape of coddling, as was possible. This kind, however, was easily spoilt by the wind and rain, and soon deteriorated under pot culture, so that he advised a fresh stock every year or so.

Lilium auratum, the Golden-rayed Lily of Japan, was the grandest of all, whether for pot culture or in the open ground. Unfortunately, this variety deteriorated after a few years under pot culture; in fact they were never so good as the first season when imported, and those who wished to keep up a good show would do well to purchase a few bulbs each autumn. The *speciosum* group, which annually flowered from the end of July to the end of September, a time when they were of the utmost value, did, as a rule, remarkably well under pot culture, and, what was more, were not so liable to dwindle away as the former varieties. Cold pits or frames were the best places to grow *auratum* and *speciosum* until they got too tall, when they should be removed to a cold house and kept near the roof. After passing out of flower the pots were often placed outside in some out-of-the-way corner, and probably got no water for days or, it might be, weeks should the weather set in dry. This ought not to be so; such a sudden withholding of water was detrimental to the bulbs, and those that flower in the early spring months, say up to May, should be given frame treatment for a time or until warmer nights set in. These varieties should be shaken out and repotted towards the end of October or early in November before root action again began.

No plants, he said, were more suitable than Liliums for the embellishment of the flower garden, and nearly all the family were hardy, provided the soil was well drained. Given a fairly good loam, the majority of them would thrive, and the cultivator could add peat and well-decayed manure, which the greater number of Liliums revelled in, underneath as well as a top-dressing. In choosing a position for *auratum* and other tall-growing kinds, preference should be given where they could be slightly shaded from the midday sun and from south-westerly gales. Generally speaking the finest examples were to be found growing among beds of *Rhododendrons* and *Azaleas*.

Dealing with the planting of the bulbs, Mr. Mayne said that the earlier in the autumn the better for the majority of the Liliums, as well as for the display of the first season. Beds that were entirely devoted to Liliums should have a carpeting of some plant or other during the summer months. These lovely bulbous plants grew and flowered in almost any position. The majority of them were inexpensive, which placed them within the reach of all possessing a garden, be it ever so small.—("Devon and Exeter Gazette.")

BIEL HOUSE.

AT a distance of six miles from the royal burgh of Dunbar is Biel House, one of the seats of Mrs. Hamilton Nisbet Dundas Ogilvy. The extensive estates owned by this lady in East Lothian were acquired by purchase in 1663 by Sir John Nisbet, then the most eminent lawyer at the Scottish bar, and afterwards a Lord of Session and King's Advocate. These estates include besides Biel House, Archerfield House, Winton Castle, and the ancient ruin of Dirleton Castle, formerly a seat of the Anglo-Norman family of De Vallibus. The mansion is admirably shown in fig. 23, page 109.

The glory of Biel from a garden point of view is its beautiful terraces and its fine pleasure grounds. My narrative will be one rather incomplete because of a hasty survey; but, nevertheless, I was impressed with their beauty and excellent keeping, as I have never seen a terrace garden more after my own ideas as regards summer brilliance than this. In the early days of September I paid my visit, and Mr. Muir, who has held the post of gardener here for a number of years, is to be congratulated on the condition and well keeping of the garden and grounds. The house is one of considerable length, and the terrace runs along the whole of the southern front. The upper terrace is a broad gravel walk edged with Box, and in wide borders on each side are bedding plants in great variety in bold distinct masses; no mixture whatever, and each is allowed to display itself. To those who have not practised or seen this style, it is especially recommended as far superior to alternating different species of plants in the same group or bed. The plants used were Golden Feather, *Perilla nankinensis*, *Petunias*, single; *Pentstemons*, *Heliotrope*, *Calceolaria* Golden Gem and *Calceolaria* Sparkler; tuberous *Begonias*, *Ageratum*, *Iresine* Lindenii and *Iresine* Herbstii; Sweet Alyssum, *Cuphea* platycentra, *Carnations*, and the following Zonal *Pelargoniums*—Henry Jacoby, *Vesuvius*, *Amaranth*, Mrs. Turner, Mrs. Mappin, Bijou, Flower of Spring, with the Ivy-leaved Madame Crousse.

A balcony from one of the upper rooms of the house had a group of plants composed of two large *Araucaria excelsa*, a large *Hydrangea hortensis*, *Fuchsias*, *Eucalyptus globulus*, Zonal *Pelargoniums* and blue *Lobelia*. A large clump of Pampas Grass was near the kitchen door, which is exactly in the centre of the house, whence a cross walk leads to the lower terrace, which is mostly planted with herbaceous plants. At the top of the steps leading to the second terrace were two large *Fuchsias* in 16-inch pots, and two curious, yet beautiful, vases, whose sides were *Echeveria secunda* glauca planted in a framework of wire. The mouth of the vases was overflowing with the brilliant crimson of Henry Jacoby Zonal *Pelargonium*.

Close to the house walls *Fuchsia Riccartoni* was flourishing, and great squares of *Tritoma Uvaria* with their glowing spikes. The back border on one side of the kitchen door for a considerable distance was filled with annuals—*Scabious* (German), *Asters*, *Coreopsis Drummondii*, *C. tinctoria*, *Gaillardias*, *Jacobæas*, *Nicotiana affinis*, with annual *Sunflowers*, *Dahlias*, *Gladiolus gandavensis* hybrids, *Chrysanthemums* Madame Desgrange and G. Wermig. These borders on the upper terrace were at least 10 feet in width, and presented a most gorgeous mass of colour. On the walls of the house were a large *Magnolia grandiflora* in flower, as well as *Kerria japonica*, *Jasmines*, and the fiery *Tropæolum majus*. An arbour near the kitchen door was overcanopied with *Clematis viticella* in flower. The castellated wall bounding the upper and lower terrace had overhanging its summit large bushes of *Juniperus sabina* variegata and *Cotoneaster microphylla*, while in the front of the wall on the higher terrace for the greater part of its length was a broad belt of *Tritoma Uvaria*.

Below these terraces are the pleasure grounds, formed by a valley with an intersecting stream. Along the sloping banks in the vale are many noble trees. Immediately in front of the house is one of the largest Cedars of Lebanon in the country; it is 60 feet high, has a spread of branches of 80 feet, and is 18 feet in circumference at the base, and was planted in 1810. Other noble Cedars of Lebanon are here, and the following also of large dimensions were noticed:—*Cedrus deodara*, *Wellingtonia gigantea*, *Libocedrus decurrens*, *Cupressus macrocarpa*, *C. Lawsoniana*, *C. nutkanensis*, *Araucaria imbricata*, purple Beech, two *Quercus Ilex*, Box trees, and Portugal Laurels, all in view from the terraces, and they proclaim the fertility of the soil of this part of East Lothian.

The kitchen gardens at Biel are small, and there are no fruit houses, the family wants in these respects being supplied from Archerfield and other places (Bloxholm Hall, in Lincolnshire, is another seat of Mrs. Hamilton Ogilvy). The houses at Biel are not extensive, and are devoted to plants, of which the general arrangement is artistic. There are no bare places; all unsightliness is hidden. One house, 35 feet long, had the front part of the roof covered with *Gloriosa superba*, with vermilion flowers; and the upper half of the back wall was clothed with *Allamanda Schottii*. This house contained large specimen *Crotons*, *Dracænas*, and *Pandanus Veitchii*, perfectly clean and healthy. *Caladium argyrites* and *Carex japonica* variegata furnished the fronts of the stages, and the *Caladium argyrites*, in 4½ inch pots, were very fine. Another house had a large *Areca lutescens* as a centre, around which was a bank of *Adiantum cuneatum*, rising up a foot from the ground; the lowest shelf was placed at that distance, and the highest at about 5 feet. *Coleus* were planted in front of the stages, which is a rather unusual but effective

plan, though perhaps they were not so bright in colour as when fully exposed to the light. A large *Clerodendron Thompsoni* was in flower in this house.

A span-roofed structure was filled with healthy *Crotons* in great variety. Amongst those I observed were Queen Victoria, Golden King, Mrs. Dorman, Weissmanni, Lord Derby, Countess, angustifolia, and elegantissima. There were also several very fine plants of *aigburthensis* and *picturatus*, grown to single stems and staked. Their height would be from 3 to 4 feet without the loss of a single leaf. Several exceptionally fine *Acalypha musaica* in 6-inch pots, clothed to the rim with leaves and having side branches naturally formed, were very conspicuous. *Eulalia japonica* variegata was represented by scores of admirably grown plants in 6-inch pots, and the stages were profusely draped with *Panicum variegatum*. Underneath *Pteris cretica albo-lineata* was growing luxuriantly in company with other Ferns and *Coleus*.

There were also houses filled with *Eucharis* and *Pancratiums*, *Tomatoes*, *Cucumbers*, and a lofty span-roofed conservatory in two divisions. The first division entered had along its rafters *Tropæolum* Ball of Fire, and at least a hundred superb tuberous *Begonias* on the side stages in 7-inch pots. They were remarkable for the size of their double flower and their profusion of bloom. *Fuchsias* occupied the central stages, and on the side stages were Zonal *Pelargoniums* and *Lilium auratum*, edged with fine plants of *Campanula isophylla alba*. The next division contained *Camellias*. The roof was covered with Gloire de Dijon, climbing *Niphetos*, and *Rubens* Roses. A very fine standard plant of *Datura* Knighti with large tubular-shaped double flowers was also in this house. Six hundred *Chrysanthemums* are grown at Biel, and all were in good health.—F. STREET.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 31ST.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Mr. Veitch, Mr. Bennett-Poë, Dr. Muller, Rev. W. Wilks, Prof. Farmer, Mr. Michael, Prof. Balfour, Mr. A. Sutton, Rev. Prof. Henslow, Hon. Sec.; visitor, Mr. L. Sutton.

Potato grafting.—Mr. A. Sutton read an interesting paper on the results of grafting and hybridising Potatoes with Tomatoes. The following is an epitome of his results:—1, Maincrop Tomato was grafted upon Victoria Potato. The tubers thus formed by Tomato foliage only were very small. 2, *Solanum nigrum* grafted on Victoria; and 3, Egg plant, *Solanum esculentum*, grafted upon Supreme, produced tubers equal to the types.

Potato hybridising.—1, Woodstock Kidney was first grafted upon the Tomato, Earliest of All. The Potato flowers were pollinated by Tomato. The seed produced Potato plants with small and subsequently diseased tubers. They were quite round. The foliage resembled that of many other Potatoes. 2, With a similar graft, the flowers were self-fertilised. The resulting produce resembled Woodstock Kidney.

Solanum Maglia hybrids.—Some hundreds of flowers were pollinated from Potato flowers. Two seedlings only were obtained; one perished, the other produced a small tuber, which improved subsequently, but was much inferior to commercial Potatoes.

Solanum tuberosum.—The tubers received in 1887 were very small, but have now attained a marketable size.

Curious varieties of Potatoes.—Mr. Sutton also exhibited three kinds of Fir-Apple Potatoes. These are interesting as taking the form of rhizomes with projecting points under the eyes, giving a scale-like appearance. One kind has several branches. These Potatoes bear flowers, but produce no berries, the foliage resembling that of ordinary Potatoes. Another variety, received from Africa, was mottled in colour, and resembled the Fir-Apple Potato. The foliage is exceedingly dark coloured, and resembles that of the Stinging Nettle.

Tomatoes raised from grafts on Potato.—Victoria grafted with Tomato Maincrop. In two years seedlings bore fruit, but very distinct from Maincrop, the leaves being decidedly smaller, the fruit more numerous but smaller and earlier, also more corrugated. These differences became more pronounced in the following year. A unanimous vote of thanks was accorded to Mr. Sutton for his interesting and valuable paper.

Hollyhock disease.—Leaves attacked by *Puccinia malvacearum* were received from Mr. E. Molyneux; the mildew which has proved fatal to these plants for many years.

Cyclamen fasciated.—Dr. Masters exhibited specimens of this not unusual phenomenon of several flowers with leaves on the same stem.

Eucalyptus sp.—He also showed flowering specimen of *E. cordatus*, growing in the open in County Down; and of *E. globulus*, grown for forty years in Leicestershire. Prof. Balfour observed that on the coast of Ross-shire several plants characteristic of the Riviera thrive well, in consequence of the amelioration of the climate by the proximity of the Gulf Stream.

Cypripedium.—Dr. Masters also exhibited a blossom of a *Cypripedium*, in which the two normally coherent sepals were free.

Additions to the Library.—"Silva of North America," by C. S. Sargent, vol. xii, Coniferae; "Orchids of Sikkim-Himalaya," by G. King and R. Pantling, parts 1-4; "Bush Fruits of America," by F. W. Card; "Sketch of the Evolution of Our Native Fruits" (America), by L. H. Bailey; "Fertilisers," by E. B. Voorhies; and "Nouvelles Archives du Muséum," Tome Dixième.

THE N.C.S. AND INCURVED VARIETIES.

ON reading the Chrysanthemum notes in the Journal of the 2nd inst. I was rather surprised to find "Sadoc" taking objection to The Egyptian being included in the incurved section, and I rather expect he has not seen it in its true character. I have not seen many blooms of it staged, but it has been present in winning stands—first prize stands I believe—in the principal incurved class at Bristol for the past two years in typical form.

As to actual experience with it we grew one plant last year which carried three first-rate flowers as true to the incurved type as they could possibly be, and required scarcely any dressing. I should class it as being in the first rank of its section, and should say it would compare favourably with any variety we have, provided it keeps up to the high standard at which I have seen it.

I quite agree with "Sadoc" that the N.C.S. is sailing rather close to the wind with regard to some varieties that are included amongst the incurved, many of them requiring an amount of labour and patience to make them even presentable on the board, and are scarcely a credit to the section when there. As to varieties of The Egyptian type I should say the more of them the better.—J. WILKINSON, Bristol.

COMPLAINTS AND GRIEVANCES RE THE N.C.S.

WE have received another list of complaints on the past delinquencies and recent shortcomings of the N.C.S. As to the past it will be better to consider it as buried, as no possible good can be done by attempts at resuscitation, especially as it seems that a rule was adopted to prevent the recurrence of one of the practices complained of.

Among recent grievances is one stating that a certain exhibitor had a "gold medal" attached to the exhibit for which it was awarded four hours before the awards were placed on those of other trade growers. This we are in a position to explain, as our reporter happened to hear all that transpired on the subject.

The gold medallist, seeing that the judging was completed, at once stepped up to the Secretary and was told, in answer to a question on the subject, that he was awarded the gold medal. "Then," rejoined the exhibitor, "I suppose I may put on the card?" The response was, "Certainly," and the card was promptly obtained and attached by the exhibitor, not by the Secretary. It was on the eve of luncheon, and the official awards were not placed on the exhibits till afterwards. The particular exhibitor was "smart," no doubt, but so far as we can see his action was quite legitimate. If another exhibitor had acted similarly in a quick inquiry, and the Secretary had refused a reply of the same nature, he would have been open to the charge of "favouritism."

Another complaint has been made to us at least a dozen times, but we have not published it mainly because of the peculiar forms in which it has been presented. The grievance seems to be so keenly felt that we publish it now, as it is well to go to the bottom of things so far as this may be fathomable. This, then, is the terrible grievance—namely, that long notices appear in the columns of the London daily papers of the exhibits of one particular trader, while those of others are either passed or receive scant attention. If these notices were supplied by show officials the charge would be grave, but they are again the result of smart trade enterprise.

The gardening Press reporters recognise the merits or otherwise of what they inspect, and not only do not want any prompting, but would reject attempts in that direction; but it is totally different in the case of reporters for the "dailies." These ubiquitous individuals are glad to get hold of an expert to point out objects specially worthy of notice, and it is no secret to those who know that there are always expert exhibitors ready to get hold of them; indeed, it is not a little amusing to observe the finessing that is resorted to to "catch the speaker's eye"—or, rather, the reporter's ear.

This is not the case at the N.C.S. shows only, but at all important exhibitions, metropolitan and provincial. The editor and reporters of every gardening journal, when reading reports of horticultural shows in the "Morning Trumpeter" or "Evening Swaggerer," know very well who have been the prompters and inspirers. It may all seem wicked; but the world and its ways have to be taken as they exist, and the time does not appear to have arrived when a reporter's guide, philosopher, and friend will pass by his own splendid exhibits as only worthy of scant mention, and sing the praises of those of competitors which may or may not be better or worse than his own.

Whether the complainants of daily Press reports would act differently or not we cannot tell; but we should know if we read the reports of shows at which they had obtained the oft-coveted position of chaperon, perhaps to some fascinating young lady with a note-book. Now having pricked the bubble of the daily paper reports complained of, we cannot refrain from the expression of opinion that those who continue to indulge in their grievances against them will seem to be engaged in something like the quixotic exercise of tilting against windmills.

Other matters of complaint we have before us relate to the N.C.S. official selections and classification of Chrysanthemums. On these subjects a complainant writes:—"In the Year Book of the N.C.S. we find varieties which were not deemed worthy of a certificate given in the selections of the best, whilst varieties which have been certificated, both by the N.C.S. and R.H.S., are omitted." This is attributed to favouritism accorded to one exhibitor, and prejudice indulged in against another. We should require strong unbiassed testimony in support of the truth of such extraordinary allegations before admitting them as facts.

That such opinions exist is undoubted, and surely all will agree that it is better they should be fully known than passed from mouth to mouth, not being modified as they go, as if certain individuals had abused their position as responsible officials. We cannot possibly believe that this is the case, and it could not be without the presence of enemies in the camp, who would, with whatever object, be sapping the foundations of any society with the conduct of which they happened to be entrusted.

Reverting to the admittance of non-certificated varieties into officially recommended lists, and the exclusion of those which have been honoured by Floral Committees, we have no difficulty in agreeing with our correspondent when he says, "This does not say much for the value of certificates." It obviously does not, but savours rather of something like a stultification. The apparent conflict in estimating the merits of varieties is, however, perhaps explainable: as the matter stands it suggests either that there are some "experts" wiser than Floral Committees, or that the members of these, assuming that they made the selections, are expert in changing their minds.

Attention is also drawn to the "unwarrantable haste" in rushing novelties into the incurved section, one of which is "not to be distributed till 1900," while others are excluded, and one at least that has been certificated, both by the N.C.S. and R.H.S. We have no means of accounting for such decisions, whether they are right or wrong. We know they ought to be right, but our complainant evidently thinks they are not, because he says, "It is these little sins of omission and commission that the trade generally find so annoying." And he goes on to say, "A society styled 'National' should not allow favour to be shown to any firm, nor permit a representative of any firm on committees for selection and classification."

We did not know that such was the case; but assuming, for the sake of argument, it to be so, we should expect that any person having interest in anything placed before the Committee would promptly leave the table pending the consideration of the product. This is the custom at the R.H.S. Committees, and many persons besides ourselves will be surprised to hear it is not the same at the N.C.S.

In cases of grievances we wish to be absolutely fair to both sides interested, our only object being the elicitation of truth and the rectification of any imperfections in an amicable, business way.

Only when societies are widely trusted can they be permanently strong and satisfactorily fulfil the object for which they are established.

NATIONAL CHRYSANTHEMUM SOCIETY.

ANNUAL MEETING.

ON Monday evening last the annual general meeting of this Society was held in St. Stephen's Hall, Royal Aquarium, Westminster, Mr. C. E. Shea presiding. In spite of the weather there was an excellent gathering, and the tone of the meeting was decidedly conciliatory, although the interest in the proceedings was keen. Under the able guidance of the Chairman, all the business was conducted with promptitude and strict regularity, which resulted in the last item on the agenda paper being reached shortly before half-past nine.

The business commenced with the Chairman calling upon the Secretary to read the notice convening the meeting, and this was followed by the minutes of the adjourned general meeting of 21st March last. Then followed correspondence from various gentlemen regretting inability to be present. These preliminary matters being disposed of, the Secretary proceeded to read the report of the Executive Committee, as follows:—

REPORT OF THE EXECUTIVE COMMITTEE.

The close of the year 1898 finds the National Chrysanthemum Society still at the head of those societies having for their object the cultivation and exhibition of some particular flower. In common with kindred societies the N.C.S. can look back upon a year's operations in which it has maintained its prestige, and its hold upon the Chrysanthemum-loving community. Despite the incidence of a summer and early autumn characterised by a prolonged drought, and at times great heat, which gave

occasion for forebodings on the part of growers for exhibition; the Shows of the Society were well maintained, the competitors were numerous, and the blooms if lacking the fine finish seen in previous years were yet of a high order of merit. In all the departments of the November exhibition the classes were well filled, while the special prizes offered by various firms for vegetables, both at the October and November shows, brought excellent collections. All the exhibitions of the Society have been well attended, testimony being thus borne to the continued popularity of the "Golden Flower."

Your Committee are gratified in noticing evidences of a revival of interest in the incurved type, which is shown by the large number of new varieties introduced during the past few years, and particularly so during the year just closed. These new introductions, some of them apparently of cross parentage, have been vigilantly examined by the Classification Committee; and those showing decided evidence of possessing characteristics of the approved incurved type admitted to that section. Some of doubtful character are reserved for another season's experience.

afforded the members of the National Chrysanthemum Society in obtaining refreshments at moderate charges.

Acting upon an instruction passed at the last annual meeting of members, a special Sub-Committee was appointed to visit halls and other places in London, and its suburbs, with a view of ascertaining what conveniences could be offered for holding the exhibitions of the Society elsewhere than at the Royal Aquarium, and upon what terms. This Committee spent considerable time in visiting buildings, and made a searching investigation as to the facilities they afforded, with the result that they recommended the Executive Committee to transfer their shows to the Crystal Palace, Sydenham. Your Committee, while fully sensible of the advantages of greater space and clearer light afforded by day at the Crystal Palace, yet thought it expedient to retain their exhibitions at the Aquarium in 1899, especially as they had the prospect of increased monetary assistance from the directors.

Large numbers of new varieties of Chrysanthemums have been submitted for examination at the meetings of the Floral Committee, and

FIG. 23.—BIEL HOUSE. (See page 107).

Your Committee, fully alive to the fact that some of the newer introductions of the incurved section so nearly approach the older varieties in character as to render it difficult at times to determine their difference, instructed the Classification Committee to draw up a list of too-much-alike varieties, which was published in the schedules of prizes for 1898, and made obligatory upon exhibitors at the Society's shows. Finding that some affiliated societies felt themselves bound to act under this list, while some held they were at liberty to adopt it or otherwise, your Committee have had the list of too-much-alike varieties, together with a list of the incurved, classified during the past three years, put in the form of a special circular, which is to be sent to affiliated societies. In this circular they are urged to adopt the list and publish it in their schedules of prizes as binding upon their exhibitors. The adoption is optional, but it is believed many societies will decide to come under the operation of the list of too-much-alike varieties.

Your Committee have to report that they have entered into an engagement with the directors of the Royal Aquarium to hold their exhibitions in that building during the present year; the directors undertaking to give an additional sum of £75 towards the prize schedule of the November show. They have materially improved the lighting of the building, and successfully brought their influence to bear upon the new refreshment contractors, with the result that better facilities will in the future be

their qualifications for certificates of merit fully and impartially considered. The record of awards is a numerous one, despite the utmost vigilance on the part of the Committee. It has been found advisable to change the day of meeting on other than show days from Monday till Wednesday, excepting the meeting in the second week of November, which will be held on Monday the 13th.

The publication of a supplemental catalogue is becoming a necessity, as new varieties are frequently produced. This matter will be fully considered by your Committee at an early meeting.

A conference on the Chrysanthemum rust—a fungoid growth which proved very troublesome to many growers last season—was held in the St. Stephen's Hall of the Royal Aquarium on October 12th, and proved an exceedingly interesting function, and the attendance of members was large. Papers from the cultivators' point of view were read by Messrs. P. Waterer and W. Wells, and one on the scientific aspects of the rust by Mr. George Massee, of the Royal Gardens, Kew. The gathering had its advantageous social aspect also: the bringing together of the members of the Society on such occasions is a decided advantage. The papers, together with the discussion which followed, will be given in the annual report, &c, in course of preparation. The Committee are under a debt of obligation to the directors of the Royal Aquarium for the use of St. Stephen's for the purposes of the conference.

The annual dinner of the Society, held on November 30th at the Holborn Restaurant, afforded an opportunity for the attendance of ladies, and the sex was somewhat largely represented. It is an innovation which gave general satisfaction. Sir Albert K. Rollit, M.P., who presided, discharged the duties of Chairman in a manner which greatly enhanced the enjoyment of the large company. It is difficult for your Committee to give adequate expression to the sense of their obligation to Sir Albert Rollit for his ready acceptance of their invitation to preside, for his geniality, and perfect after-dinner speeches.

During the past summer your President and Lady Saunders celebrated

their golden wedding, and the hearty congratulations of the members were duly conveyed to them. The warmest thanks of the Society are due to Sir Edwin Saunders for his continued interest in the Society, and for so generously giving the first prizes in the classes in which the Holmes Memorial Cups are offered; to the directors of the Royal Aquarium for their special commemoration prizes, and to all others who in this helpful way enabled some new features to be introduced to the schedules of prizes.

The financial statement and balance-sheet having been printed and circulated among the members prior to the meeting, it was not considered necessary to read it in detail, but was taken as read.

Audited and found correct { A. E. STURBS.
JOHN R. CHOLMELEY. January 20th, 1899.

Before any discussion took place the Chairman reminded the meeting that he had not been in close touch with the doings of the Society for several years, and when asked to occupy the post he first thought he was hardly fitted on that account to occupy it, but upon consideration he

thought his very freedom from close contact with their work might make him the most independent of chairmen, especially as the agenda showed that there might be some knotty points for discussion. He then commented briefly on the critics, and reminded them that all

criticism is not unfriendly; he also alluded to various items in the balance-sheet. There was nothing to be brought forward that could not be discussed, and he hoped the speakers would keep to the point, and say what they wanted in speeches as short as was consistent with their ideas.

Mr. W. Seward proposed, and Mr. Outram seconded, the adoption of the report and the accounts as submitted.

Mr. Moorman, comparing the accounts with those of the previous year, felt proud of the balance-sheet placed before them, and thought no one could charge them with extravagance. Among other things, he thought that some reference in the annual report should be made of the report submitted by the Sites Committee, and this was subsequently arranged to be done by the insertion of a paragraph in the report. Mr. Dean, replying to several of Mr. Moorman's queries, showed that a large proportion of arrears had come in since the accounts had been made up. When put to the vote the report and accounts were carried unanimously.

A vote of thanks was then carried for the way the auditors had vouched the accounts, and Mr. Stubbs, the retiring auditor, replied, expressing the hope that they might never be less favourable than this year.

Elections of officers next followed, with the following results:—President, Sir Edwin Saunders. Treasurer, Mr. T. Wilkins. Chairman of Committee, Mr. P. Waterer. Vice-Chairman, Mr. T. Bevan. Secretary, Mr. R. Dean. Foreign Secretary, Mr. Harman Payne. Auditor, Mr. Berridge. One-third of the Committee retiring in turn resulted in a large number of nominations, the following gentlemen being elected, with the number of votes each one obtained:—Mr. E. Beckett, 107; Mr. C. Gibson, 100; Mr. H. J. Jones, 98; Mr. A. Outram, 97; Mr. D. B. Crane, 95; Mr. Davey, 94; Mr. Kenyon, 81; Mr. T. W. Wilkinson, 78; Mr. J. McKerchar, 73; Mr. C. Blick, 70; Mr. Simmons, 62; Mr. A. Wright, 61; Mr. G. Walker, 54; Mr. Sturrock, 52. Four Scrutineers—viz., Messrs. W. Seward, Pinches, Holmes, and Weeks—were appointed to conduct the ballot.

Upon the motion of Mr. Moorman it was resolved to add the name of Mr. T. W. Sanders to the list of Vice-Presidents.

The proposed alterations to rules then followed, the only substantial alteration being in rule ix, which now gives definite authority to delegates of affiliated societies to vote at general meetings. Representatives of affiliated societies strongly urged the importance of this, Messrs. Rundell, Broughton, and several others maintaining the claim.

PROPOSED ALTERATIONS OF RULES.

The following additions, &c., to the Rules, of which notice had been given, were considered:—

II. OBJECT OF THE SOCIETY.—The special object of the Society shall be to promote the cultivation of the Chrysanthemum—(1) by means of exhibitions; (2) by awarding certificates of merit and medals at the exhibitions of the Society and the meetings of the Floral Committee; (3) by the publication as necessary of an official catalogue of select cultivated varieties for the guidance of Chrysanthemum growers in matters of classification and nomenclature; and by such other means as the Committee may from time to time see fit to adopt.

Alterations proposed by Mr. W. Wells.

Rule II.—Second line, delete "promote," substitute *encourage*.

Third line, after medals, add, *to Chrysanthemums only, and which have been grown by the exhibitor, or exhibitors*. Lost.

III. MANAGEMENT.—The management of the Society shall be vested in the officers of the Society—viz., a President, Vice-Presidents, Treasurer, Chairman, and Vice Chairman of the Executive Committee, a Foreign Corresponding Secretary, and an Executive Committee of thirty-six members, and the representatives from affiliated societies in accordance with section 1 of Rule X. The President, Treasurer, Chairman, Vice-Chairman, and Hon. Foreign Corresponding Secretary shall be *ex-officio* members of the Floral and all Sub-Committees. At all meetings of the Society and Executive Committee nine persons shall form a quorum for the transaction of business, and three persons at all meetings of Sub-Committees.

Additions proposed by Mr. R. Dean.

Rule III.—Third line, add after Foreign Corresponding Secretary the words, *and General Secretary*. Seventh line, add after Foreign Corresponding Secretary the words, *and General Secretary*. Withdrawn.

IV. MODE OF ELECTION.—The President, Treasurer, Chairman, Vice-Chairman, a Hon. Foreign Corresponding Secretary, and a General Secretary shall retire from office annually, but shall be eligible for re-election; any member may nominate a candidate or candidates to any of the foregoing offices. One-third of the members of the Executive Committee shall retire annually, but shall be eligible for re-election provided they have made four attendances during each year of office; the retiring officers and members of the Committee shall be considered as nominated, if eligible, unless they have expressed to the Secretary in writing within fourteen days of the annual meeting their intention to retire. The votes of the members present at the annual meeting shall be taken by means of voting papers, on which shall be the names of the retiring officers and Committee, and be collected and counted by Scrutineers appointed by the meeting.

Addition by Mr. W. Wells.

Rule IV.—Tenth line, after "The votes," to read, *to be taken by means of voting papers which shall be sent to every member who has paid his subscription seven days previous to the annual meeting, containing a list of all matters upon which their vote is required; the same duly filled in to be returned to the Secretary three days before the annual meeting*. Lost.

IX. PRIVILEGES.—All Fellows and members shall be entitled to vote at the general meetings of the Society. Fellows shall be entitled to four passes; members subscribing half-a-guinea to two passes; and those subscribing 5s. to one pass, to all the Society's exhibitions and meetings of the Floral Committee.

Amendment recommended by the Executive Committee. Mr. Taylor seconded.

The first line to read, *Fellows and members only shall be entitled*.

Lost.

Rule IX.—Although the proposed amendment was lost, an amendment was carried by which it now reads: "All Fellows, members, and delegates of affiliated Societies only shall be entitled to vote," &c.

PRIVILEGES, 1.—To appoint one of its members as a delegate to the Executive Committee of the National Chrysanthemum Society, with power to vote at all meetings, unless otherwise specified.

Amendment recommended by the Executive Committee.

First line after "its," delete "members," and add, *bona fide subscribers*. Carried.

Rule X. CONDITIONS, 1.—That the Society's medals and certificates be awarded only to classes for plants of cut blooms of Chrysanthemums, and that all inscriptions be recorded thereon before being handed to the winners.

Amendment by Mr. Wells.

That the Society's medals and certificates be awarded only to classes (or miscellaneous exhibits), which have been grown by the exhibitors, or been in his possession for at least three months. This condition shall also apply to exhibitors at the National Chrysanthemum Society's shows, and that all inscriptions, &c., &c. Lost.

XII. EXHIBITIONS.—The exhibitions of the Society shall be held at such times and places as the Executive Committee may from time to time determine; and the most recent issue of the Society's catalogue and the latest report of the Classification Committee published in the last annual report or year book shall be the standard work of reference in all questions of classification and nomenclature that may arise thereat. The money prizes, medals, or other awards won by exhibitors at any of the exhibitions shall be delivered to the winners thereof within thirty-one days from the date of such. The Executive Committee shall make such regulations as may be deemed necessary for the orderly management of the exhibitions, and shall have power to alter or amend such regulations whenever it may be deemed desirable.

Alteration proposed by Mr. W. Wells.

Rule XII.—Seventh line, delete "won by," and substitute *awarded to*. Lost.

XIV. SCHEDULE REVISION COMMITTEE.—A Sub-Committee of the Executive Committee, consisting of nine members with the officers *ex-officio*, shall be appointed to revise the schedule of prizes and nominate Judges, and report the same to the Executive Committee for approval.

Amendment recommended by the Executive Committee, and seconded by Mr. D. B. Crane.

Third line, after "appointed" add, *at the first meeting of the Executive Committee held after the annual general meeting*. Carried.

XV. JUDGES.—Judges at the various exhibitions shall be appointed by the Executive Committee, but only the elected members and *ex-officio* officers can vote for the same.

Amendment recommended by the Executive Committee. Mr. Moorman seconded.

Add to third line, *The votes shall be taken by means of voting papers*. Carried.

Addition proposed by Mr. W. Wells.

XV.—Add at end, *No Judge to be a member of any Committee of the National Chrysanthemum Society*. Lost.

XVII. THE ACCOUNTS OF THE SOCIETY.—The accounts of the Society shall be kept by the Treasurer and General Secretary, and be closed on the 31st of December. All moneys shall be deposited at a bank to the account of the Society, and all accounts be passed by a Finance Sub-Committee, consisting of the *ex-officio* officers and three members of the Executive Committee, and paid by cheque which shall bear the signatures of the Treasurer and General Secretary. The accounts of the Society shall be audited prior to the annual general meeting by two competent persons appointed at the preceding general meeting, and the said accounts shall be printed and issued to the members at least seven days previous to this meeting. No Auditor shall hold office longer than two years consecutively. The Executive Committee shall determine annually the amount of salary to be paid to the General Secretary.

Amendment recommended by the Executive Committee, and seconded by Mr. Moorman.

Fifth line, after "Treasurer and General Secretary" add, *such Sub-Committee shall be elected annually after the first meeting of the Executive Committee held after the annual general meeting*. Carried.

Amendment by Mr. W. Wells.

Seventh line, insert, *together with any proposition made for altering the rules, or any new members who have been proposed prior to that date*. Lost.

New rule proposed by Mr. W. Wells.

XX. *The Secretaries' duties, &c.*

This was irregular in form and could not be received.

New members were elected, and three Societies—viz., Taunton Dean, Totter, and Blackburn—were admitted in affiliation. This concluded the business, and, replying to a vote of thanks, the Chairman complimented the meeting on the way the proceedings had been carried through.

AUSTRALIE AND MR. T. CARRINGTON.

THE Classification Committee of the N.C.S. has bracketed these two varieties as being either "synonymous, or too-much-alike," which is surely an error. In spite of the classification, Mr. T. Carrington will forge for itself a reputation, and will occupy a prominent position. It is quite distinct from *Australie*, both in colour and form. The former is richer and clearer, the florets are smoother and more even, and they are less whirled, and no judge could have the least trouble in noticing a difference between these two.

They are much more distinct than *Pride of Madford* and *Duke of York*, or *Mrs. Mease* and *G. J. Warren*; in fact, a bloom from an early bud of the latter could easily be shown as *Mrs. Mease*, and without doubt has been done with success. Of course I do not argue that *G. J. Warren* and *Mrs. Mease* should be bracketed as too-much-alike, but that *Australie* and Mr. T. Carrington are distinct.—W. J. GODFREY.

CAN IT BE TRUE?

THE other day a leading morning paper recorded the wind-up of the affairs of a suburban *Chrysanthemum* society, which took place prior to disbanding. The failure of a *Chrysanthemum* society at all is something novel, but the decision arrived at by the members of this particular body may sound even more astonishing. It was to the effect that they were of the opinion that the *Chrysanthemum* craze is on the wane and the public popularity of the flower declining. I wonder what the champions of the autumn queen have to say to this? It may be only the pessimistic cry of an unsuccessful society, who attribute the failure to the change of public taste. Be that as it may, the announcement was boldly made, and will, perhaps, lead many to wonder whether the reign of the autumn queen is approaching its end. *Dame Fashion* is fickle, and takes unlooked for courses sometimes.—G.

CATALOGUES AT SHOWS.

IN reference to your report of the shows and meetings of the People's Palace Horticultural Society (page 93), I desire to say that, while I wish all success to the Society, I am bound to protest against the action of the Secretary or judges, under the following circumstances:

I was asked to favour the show with an exhibit "not for competition." I sent six dozen cut blooms, and, as is customary at shows generally, my representative placed some of my catalogues by the side of the exhibit for the people to take. When the judges came to them the catalogues were at once thrown under the table and not allowed to be distributed. The Society is affiliated with the N.C.S., and the judges, as stated in your report, were Messrs. R. Ballantine, R. Dean, and T. W. Sanders.

I have written to Mr. C. E. Osborn, the Secretary, and as I cannot get a satisfactory answer, I now publicly ask the Committee if they sanction such an extraordinary proceeding as I have described? I, with other non-competitive exhibitors, have distributed catalogues at most of the best shows in the kingdom, and this is the only instance known to me of such summary action.

I should like to know who threw my catalogues under the table, and why? Also if any exhibitor, who was invited to assist a show, has ever been similarly treated before?—W. WELLS, *Earlswood*.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

ON Wednesday, the 1st inst., the annual meeting of this Society was held, when a large number of the members testified their interest in the Society by attending to take part in the election of the Committee and other officials for the current year. Mr. John G. Newsham was elected to the chair, and commenced the business by calling upon the Secretary to read out the statements of accounts which had been previously passed by the auditors.

Favourable weather (for November) at the last show, which was, as a whole, much better than previous ones, brought a large number of visitors together, and resulted in increasing the funds of the Society, and the balance of cash in the bank and the Treasurer's hands is £24 more than at the corresponding date last year. The Society is financially and numerically in a better position than it has ever been since its foundation. Its cash balance is now £70 12s. 4d., with a reserve fund of £50 13s. 9d. In consequence of the uncertainty of the weather at the time the Society's shows are held, it is considered advisable to further increase the reserve fund to provide for the proverbial "rainy day," which it is, however, hoped will not put in an appearance for a long time to come.

C. E. Jeffcock, Esq., the popular President of the Society for some years past, has thought it advisable, in consequence of removing from Sheffield, to resign the presidency, and in future take up a position amongst the V.P.'s. The alteration was greatly regretted by the Society. W. A. Milner, Esq., J.P., of Totley Hall, was unanimously elected President in the place of Mr. Jeffcock. Mr. Milner, of Daffodil fame, who has always taken a great interest in the Society, will be a most valuable and popular gentleman to be at the head of

the officials, who are fortunate in being able to get him to accept his present position.

With two exceptions in the Committee the whole of the other officials were re-elected. The annual dinner will take place on the 18th inst. in the Masonic Hall. The proceedings terminated with a vote of thanks to the Chairman.—J. H. S.

SWEET PEAS.

How popular these flowers have become is indicated by the collections, trade and otherwise, seen at summer shows. The prizes given in competition for bouquets, stands for effect, and dinner-table decorations at Shrewsbury and elsewhere are encouraging, and as the flowers can be grown by the cottager as well as by gardeners they have become highly popular. No flower lends itself better to a greater variety of uses than these, and what a range of colour!—from purest white to deepest purple in every shade imaginable.

As the time approaches when cultivators are busy laying plans for seed sowing, a few hints may be acceptable on growing Sweet Peas. Where early flowers are needed, it is usual to sow in October; but if a few seeds are mixed with soil thickly, and kept moist in a warm house, they will soon be on the move; gradually harden before transplanting, or the reaction in consigning them direct to the ground would be injurious. A trench should have been prepared on a south border or in a warm nook, with well decayed manure as a base. Over this place some old potting soil, or any such mixture that is light and fairly dry. Level down, and then carefully sow the mixture of sprouted Peas and soil together thinly over the width of the trench, covering with about 2 inches more of the old potting soil. The plants will soon be through, and as the sides of the trenches are considerably higher than the growing Peas, these will be sheltered from the keen March winds.

I do not favour dense shelter, such as Yew or Fir boughs, in too close proximity to the Peas, as these must necessarily cause them to grow spindly; rather use in preference a few well twigged tops of Hazel boughs rather thickly, and, where possible, use new sticks, as the plants never take so kindly to old ones as to these. It is half the battle to encourage free early growth. For later crops the sowings should be made at an interval of six weeks, say early in March and late in April, in prepared trenches in the open. Sow thinly, and allow each plant full scope for development; otherwise, instead of having finely developed flowers on long stalks, they would, on the contrary, be short-stalked, bearing at best pairs of undersized flowers only.

Nothing pays better for liberal treatment than the Pea tribe. In dry periods good waterings are necessary, using either diluted liquid manure or some fertiliser, such as soot, in moderation, the rows to be afterwards mulched with short manure. A cooler situation is advised for the last sowing, or the plants suffer considerably from heat and drought in dry summers. When wanted for embellishment the flowers need cutting early in the morning, as they retain their freshness much longer.

Birds, mice, and weevils are enemies of the plants, and need watching and guarding against. Especially does this apply to the first sowings, when food in the form of green stuff runs scarce.

As regards varieties, these are too numerous to particularise. With American introductions, such as *Blanche* and *Sadie Burpee*, the selection may be both varied and beautiful.

A stand well set up of Sweet Peas mingled with light feathery Grasses, or the graceful inflorescence of *Gypsophila paniculata*, with *Smilax* or *Maidenhair Fern*, cannot be surpassed in beauty by the rarest Orchids. It is possible to secure a long continuation of the flowering period by keeping the pods closely picked off. A few seeds in 9 or 10-inch pots sown now and grown cool will give flowers a few weeks earlier than those treated outside, and are very effective.

I do not care for the dwarf Cupids, the flowers drop so soon after opening, besides the plants being somewhat miffy. I should be glad to know if that is the general opinion of cultivators who have tried the pigmies, which I do not consider worthy of space in the garden.—A MIDLAND GARDENER.

BIRMINGHAM GARDENERS' ASSOCIATION.

THE thirteenth spring session of this Society was inaugurated on the 30th ult. by a fairly well attended meeting of the members to listen to a dissertation by Mr. John Pope, F.R.H.S., King's Norton, entitled "Discussion on Pots, Potting, and Soil Mixtures." The subject embraced detailed description of the shapes, quality, and sizes of pots, also glazed versus soft or porous pots, the former being much affected by *Auricula* growers especially. Potting and soil compounds were also dealt with at considerable length; and concerning the act of rapid potting, the lecturer instanced the fact that once when on a visit to America, the late Mr. Peter Henderson informed him that one of his men, for a wager, undertook to pot 7000 bedding plants, chiefly *Verbenas*, out of the propagating

house in the average day's work, and which he duly accomplished, but the exertion was so great that he had to rest for a day or two afterwards.

In the discussion which followed, one "old expert" remarked, relative to glazed pots, that when serving, upwards of forty years ago, under the late Mr. George Fleming at Trentham Hall Gardens he was placed in charge of the Pelargonium houses, and which plants were most successfully grown in glazed pots or pans, likewise stove plants. The pots were manufactured at the instance of her Grace Harriett, Duchess of Sutherland, by the firm of Minton & Co., Stoke-on-Trent, the Duchess being an enthusiastic patron of the art of pottery, especially in regard to the style indicated, and including encaustic and other ornamental tiles suitable for balconies and window boxes. Examples of specimen plants grown in glazed pots were exhibited by Mr. Fleming at one of the Royal Horticultural meetings, as evidence of the suitability and ornamental character of the pots in preference to the ordinary clay commodities. At the close of the discussion several new members were enrolled, whilst the Society's invaluable lending library was also laid under more than ordinary contribution.—W. G.

WRIGHTIA ZEYLANICA.

THIS plant is very effective when in bloom, but it does not seem to be generally cultivated in gardens. It is a member of the same family as the Vincas, the Allamandas, the Oleanders, and the Tabernæmontanas, and to the last named the flowers bear some resemblance. These are pure white, the corolla five-lobed, with a peculiar irregularly cut corona-like appendage at the base of the lobes, such as is seen in other related plants. The general form of the flowers and leaves is shown in fig. 24. *Wrightia zeylanica* requires a stove temperature, and being of loose habit, though not a climbing plant strictly speaking, it succeeds best trained to the roof of a house. A compost of turfy loam and peat or leaf soil and good drainage are requisite whether it be planted out or in a pot.

THE GARDENERS' ORPHAN FUND.

AS Mr. D. T. Fish expresses on page 85 so strong and so sincere an interest, amounting to anxiety, a feeling that is no doubt very widely shared by subscribers generally, and especially in the provinces, in the Orphan Fund, I ask leave to mention how matters stand in relation to the vacant office of secretary, as was the subject of common conversation at the Drill Hall last week, and might well be regarded as an open secret. If I imagined that any harm would result to the Fund I would not now have told of these matters, but honestly believing that it is best subscribers generally should know, and as soon as possible, no excuse otherwise is needed. It may be as well to tell Mr. Fish that whilst there can be no doubt his great interest in Mr. Barron and the office is warmly reciprocated by the latter, yet it is not a case that could be in any way got over by the measures he refers to. Mr. Barron has not resigned without good reason, though it be a reason all must regret. Still we all grow older and feebler with advancing years, and no amount of determination can stay the hand or the effects of Time.

But when it is understood that something over 200 persons applied for the reversion of the office, it is evident that there are no lack of candidates willing to assume the duties of secretary. These were reduced at the first sitting of the Selection Committee to a manageable number, and at a second sitting were reduced to six, the whole six being capable and suitable men. But the Committee had resolved to recommend to the general meeting of subscribers on the 17th one person only as the result of their examination into the merits of the whole. It was therefore important that any such selection should be of unanimous form, and after some voting over two or three names, the final selection, first by majority, and eventually unanimously, was made of Mr. Bryan Wynne, who is not an unknown person in relation to gardening, and especially with gardening literature, by any means.

Mr. Wynne was for many years on the staff of the "Gardeners' Chronicle;" then he started, in conjunction with others, the "Gardening World," and now he conducts a small, but apparently flourishing, trade advertising paper. He was for some time a member of the National Chrysanthemum Society's executive, and for a year or so Chairman of that body. His connection with the Orphan Fund is of the earliest, having from its formation been a member of the Committee, and can claim to have attended more meetings than any other member. He has probably more complete knowledge of the working of the Fund than has any other candidate, and has for several years rendered to Mr. Barron unstinted and valued help. He is not yet of advanced age, and may reasonably look forward to giving to the Fund some fifteen to twenty years of service.

Naturally those are regarded as important elements in his case that have been fully weighed by the Committee. Certainly they could not have been ignored. His selection should be as acceptable to the market trade, whose candidate was in the running a very strong one, as to the nursery trade, and to gardeners in general, as he holds a somewhat intermediate position in relation to all; but is the son of a gardener, has been a gardener himself, and is now in warm and complete sympathy with gardening in all its forms. Of course the presentation of Mr. Wynne's name to the general meeting on the 17th by the Committee does not elect to the office; that has to be done by the votes of the subscribers present, and I hope it will be the earnest desire of subscribers, having the future

prosperity of the Fund at heart, to attend at the meeting, and support the candidate thus selected by the Committee.

There is good reason to believe that there will be no opposition at the meeting. Still there is no telling what may happen, and every well-wisher to the Fund should attend, if possible, for the purpose indicated. It seems very probable that possible troubles to the Fund were anticipated had a market man, however competent, been selected, as already there is far too much coldness, on the part of gardeners generally, towards the Fund, and had such selection been made the result might have been little less than a calamity. Seeing that the Fund was originally promoted by and for the benefit of private gardeners, it is but right that its control should be largely in their hands and exercised in the interests of their

FIG. 24.—WRIGHTIA ZEYLANICA.

orphans, admitting at the same time that market men have given to the charity valued service and support.—TELEPHONE.

[In our opinion no man has given more devoted service to the Fund—and we speak from experience during the early years of its career—than has Mr. Wynne, while no one can question his capacity for the position for which he is authoritatively recommended. A unanimous vote will be of advantage to the charity.]

THE YOUNG GARDENERS' DOMAIN.

GOLD PENMEN.

WE have once more to undertake the pleasant task of announcing the successful writers in the Young Gardeners' Domain. They are two—namely, Mr. T. Payne, late of The Gardens, Luton Hoo Park, Luton, and Mr. S. Smith, The Gardens, Ruxley Lodge, Esher, both of whom by persistent effort secured the requisite number of marks. The subjects with which they have from time to time dealt have been broadly diversified, and have evidenced not only creditable literary aptitude, but also thorough practical acquaintance with the various cultural details. We offer them our congratulations, and can affirm that they were not easy winners, for at least two others ran them very closely, and will with perseverance be likely to score before many more months have passed.

CUCUMBERS.

To obtain Cucumbers ready for use about the middle of April sow the seeds singly, without delay, in clean, well-drained thumb pots, filled with a compost consisting of equal parts of good loam, leaf soil, and sand, taking care not to cover too deeply. Give a good watering, but afterwards be sparing with it until the seedlings appear above the surface. Place the pots in a house, under hand-lights, affording a temperature of 65° to 70° by night, 70° to 75° by day, and when the plants are an inch in height remove them to a shelf near the glass with the same temperature as before. After the plants have made their first rough leaf, and have a fair amount of roots, pot as deeply as possible in 5½-inch clean, well-drained pots, in a compost of two-thirds fairly rough loam, and the remainder sweet horse droppings, with a little sand. Apply water if necessary, and placing a neat stake to each, keep as close to the glass as possible, as this does much to insure sturdy, short-jointed growth; shade for a few days if the weather is bright.

While the plants are growing the house, if empty, can be got in readiness to receive them. Thoroughly wash the glass and woodwork, removing old soil, if any, lime-wash the walls, and well clean the drainage. When this has been completed, turves which were cut last autumn should be placed on the drainage, grass side down, to prevent any fine soil getting amongst it. The compost which the plants are to fruit in should consist of two parts of loam cut up roughly, and the remainder sweet horse droppings, fine peat, and old lime rubble, with a slight sprinkling of bonemeal, thoroughly incorporated, and it must be placed in the house to become warmed, making it into hillocks, or a ridge the lengthway of the house, allowing room for future top-dressings. When the plants have a fair amount of roots, place them about 4 feet apart, but not too deeply, merely covering the top of the ball, and put a stake to each for support until they have reached the trellis. Afford a temperature of 65° to 70° at night, 70° to 75° by day, with a rise of 10° from sun heat; the bottom heat should be kept at 90°. After being planted it will be necessary to lightly shade for a few days from the sun.

Syringe the plants on bright days, mornings when the temperature reaches 75°, also at midday, and close the house, but in dull weather damping the paths and walls will be sufficient. Great care should be taken in ventilating. Do not admit any air until the house stands at 80°, avoiding cold draughts, as they are liable to stop the growth of the plants. Attend to the tying and stopping of the laterals regularly, removing male blooms with deformed and surplus fruit as they appear, leaving sufficient to keep up a supply. Red spider is rather troublesome, but frequent syringings will keep it in check. Fumigate about every fortnight for green and black fly, XL All vaporiser being a good thing to destroy them, but on no account overdo it. Keep the evaporating troughs charged with weak liquid cow manure. Attend to the watering, never letting the plants become dry. As the roots appear above the surface top-dress with compost as stated for planting, not adding more than an inch at a time.—P. R.

A PUPIL OF AN OLD BOY.

MOST readers of the Journal will remember the interesting series of articles contributed by "An Old Boy" during 1896. The excellent advice then given cannot have failed to benefit any young man who took the trouble to follow it out. I propose to speak of two or three of the suggestions made by him, and which, having adopted, I find of great advantage.

One of these—the keeping of a diary—is very useful. I jot down all the daily operations that come under my notice, and any other items that I wish to remember. These, together with the register of the barometer, maximum and minimum temperature, amount of rain, and general observations on the weather, form an interesting chronicle for reference on the corresponding date of the following year. Its use will at once be apparent, as one can then see whether he is forward or backward in his work, judging by the previous year.

Another subject the writer wished young gardeners to take up was drawing. He did not say what (if any) particular branch, but I think a general knowledge of the art is what is required. Being fond of drawing myself, much was not needed to urge its desirability. Freehand, model, light and shade, and design are my favourites; geometrical drawing and the like I find rather "dry," though perhaps it is the most useful.

Then "An Old Boy" recommended us to study botany—surely a large order; but I do not think he meant us all to be Lindleys and Hookers; that would take a lifetime, and more ability than many of us possess. What I think he meant was, that we should acquire such a knowledge of plant life as would help us in our work, of course extending the knowledge as much further as possible. I will just outline my *modus*

operandi, as it may possibly be of slight assistance to some who, like myself, are unable to attend a botany class, for the simple reason that there is not one held within reasonable distance. First, I wrote to the Journal, asking what book to get on the subject. The reply was, Sir J. D. Hooker's Elementary Botany, Science Primer, price 1s., published by Macmillan & Co., London. Next I bought a 7s. 6d. microscope, perhaps not the best adapted for the purpose, but still it has done good service in revealing the marvellously interesting inner life of vegetation. Then I read the book carefully through, but found it impossible to retain a tithe of the vast amount of information contained in that small volume. So procuring an ordinary exercise book, I began at the first page of the primer, and read it again, using the microscope as directed, and writing down all important points and scientific terms. By this means some of the elements of elementary botany are fixed in my brain. This may seem a crude system to many who have had the advantage of a teacher, but they must remember that I had no friend whose aid I could seek in the matter: true, I might have inquired of "our Journal," but somehow I did not think of it. We should judge by results, and I am sure that anyone, failing a proper teacher, who adopts this system, and works at it, will not begrudge the time spent. Some worthy men that I know would say that the above subjects are not necessary to make a good gardener, but that does not prove that the "good" gardener would not be a "better" if he were acquainted with them.

I wonder what they would say to a young man studying "physiography?" "Waste of time," they would exclaim; and so it might seem at first thought; but think again. Does not the science of physiography deal with the all-important elements with which a gardener has to contend—viz., the soil, the rain, and the weather? Is it possible for a man to know too much about what is so closely associated with his work? Then, again, our friend says that he has got on all right without knowing how the soil is formed, and what causes the rain and the changes of the weather. Perhaps so; but would he not be a better man for the knowledge? Would not the pleasure of life be deepened and intensified if he were able to trace this or that to its origin? And then "knowledge is power," as everyone will be prepared to admit.

I have a splendid book on this subject by T. H. Huxley, F.R.S., published by Macmillan & Co. I propose giving, with the Editor's approval, a few extracts that would, I think, interest and benefit readers of the "Domain." It touches on several of the sciences, geology, botany, chemistry, and astronomy; but not so deeply as to be incomprehensible to a fairly intelligent reader. "Physiography: an Introduction to the Study of Nature" is the title of the book. The fact that it is a study of Nature should recommend it to all gardeners, and supply the excuse (if any be required) for its mention in these columns. "An Old Boy" did not allude to this subject in his articles; but I feel sure he will readily grant what I have claimed for it.—ERICA.

FRUIT FORCING.

Cherry House.—The trees are now rapidly unfolding their buds, and will soon have a beautiful appearance. It is advisable to fumigate the house before the flowers expand, so as to make sure that the trees are free from aphides. The temperature should be maintained at 40° to 45° at night, and about 50° in the daytime regularly, a genial atmosphere being secured by damping the paths and borders occasionally. The house can hardly be too freely ventilated, subject to the temperature being maintained. If fresh trees are to be introduced they must be planted without delay, shading when the sun is powerful, and lightly sprinkling frequently to promote speedy re-establishment, surrounding surfaces also being well moistened.

Cucumbers.—Plants raised from seeds sown at the new year, and transferred from the small pots to the ridges or hillocks in the Cucumber house now or before, need not be stopped until they have reached two-thirds across the trellis. If the plants cannot yet be turned out into the fruiting quarters they may be shifted into larger pots, it not being a good plan to allow them to become cramped at the roots, and they must be transferred to the fruiting bed before these are much matted in the pots.

Winter Fruit.—The plants will be much benefited by top-dressings of fresh lumpy loam and sprinkling on a little fertiliser. Admit sufficient air in the early part of the day to insure a change of atmosphere. Maintain a night temperature of 65°, allowing 5° more when the external air is mild, and 5° less in the morning when the weather is severe; 70° to 75° by day artificially, and keep through the day at 80° to 85° or 90° from sun heat, always securing a good heat from an early part of the day, and if by early closing the temperature rise to 95° or even 100° it will benefit the plants. As the light and sun heat increase a greater supply of atmospheric moisture is needed, damping in the morning and early afternoon. Liquid manure once or twice a week will be required by plants coming into bearing; but avoid excessive soil moisture and stimulants. Thin the fruits well, remove superfluous growths, bad leaves, tendrils, and staminate blossoms, stopping the shoots one joint beyond the fruit, and in no case crowding or overcropping.

Melons.—In a Melon house a ridge the whole length of the bed, about 2 feet wide at the base, with the top flattened so as to give a depth of 10 to 12 inches, is preferable to hillocks, the soil being made firm. When warm the plants may be turned out, making the soil moderately firm about the roots and raising it a little higher than before, but not nearer than half an inch of the seed leaves. The plants can be placed about 2½ feet asunder, the leading or primary shoots being taken up without stopping until fully two-thirds of the distance they are intended to travel, then pinch out the point of each. Some varieties will show fruit on the first laterals; and, as early Melons are an important consideration, take out the point of each alternate one, the other on opposite sides of the leader being rubbed off whilst quite young at a joint above the fruit, but not until fertilised or artificially impregnated. The plants will require little water for a time; nevertheless, maintain the soil in a moist condition, avoiding anything approaching saturation. Sprinkle the paths and walls in the morning and early afternoon. Ventilate very carefully, avoiding cold currents of air, and keep the night temperature at 70°, 65° in the morning, or even 60° on very cold nights, 70° to 75° by day, rising to 85° or 90° from sun heat, and the latter to 95°, or even 100°, after closing; bottom heat to be kept steady at 85°.

Vines.—*Earliest in Pots.*—Vines started in November must be attended to, thinning directly the berries are set and removing surplus bunches early. The laterals beyond the bunches may be allowed to advance a joint or two at each development, but only foliage fully exposed to light profits the Grapes. Laterals behind the bunches should be closely stopped or removed where they interfere with the principal leaves. Top-dress with rich compost or well-decayed manure, and afford liberal supplies of liquid manure, not too strong. Where the pots are stood on brick pedestals with fermenting materials placed round the pots, the roots may be encouraged to extend by turves placed on the rims so as to form a dish, this being filled with rich material, and the roots, coming into the fermenting material, gather nourishment, which will greatly aid the swelling of the berries.

Early Houses.—Tie the shoots down carefully, not being in a hurry; but the points must not be allowed to touch the glass. Avoid crowding by leaving those growths only that can have full exposure to light, stopping the bearing shoots when two joints are made beyond the show for fruit and the leaf at the joint is the size of a halfpenny. If the space is small stop one joint beyond the bunch, pinching the laterals at the first leaf, and so on as made. Where there is room the bearing shoots may have three or more leaves beyond the bunch. The better foliage a shoot has the finer will be the Grapes. Laterals below the bunch may be removed where the space is limited, except from the two lowest leaves, pinching them at every joint. The great point is to secure well developed leaves fully exposed to light.

Vines in Flower.—The night temperature should be 65°, and 70° to 75° by day from fire heat, the air of the house being kept rather dry. Early Muscats require a night temperature of 65° to 70°, advancing 10° to 15° by day, closing the house at 80° to 85° in bright weather. When in flower every bunch should have a large flat camel's-hair brush drawn lightly over it, and if there is a deficiency of pollen that of Hamburgs should be applied. Thinning the berries must commence with the free-setting varieties as soon as they are formed, but if the Vines are inclined to produce stoneless berries thinning should be deferred until those properly fertilised take the lead in swelling. Remove duplicate bunches, leaving the best and most compact, always avoiding overcropping, and aiming at high finish.

THE KITCHEN GARDEN.

Broad Beans.—Where these are wanted extra early, there will be a considerable gain by raising plants under glass to form rows across a south border. Sow seeds of the Early Longpod singly in 3-inch pots, and place in gentle heat to germinate. Before the plants become drawn and much root-bound, they must be hardened, and the first favourable opportunity taken of planting out. Afford temporary shelter for a few days after planting. As early in this month as the ground is found to be in a moderately free working condition, sow seeds of the variety named in rows 2 feet apart. If room on a warm border cannot be afforded this crop, it may be relegated to a sunny open spot, a slope to the south answering best.

Early Peas.—If seeds of early varieties are sown now in boxes or 3-inch pots, placed in gentle heat to germinate, and eventually placed out of doors, good gatherings will be afforded earlier than any rows obtained by sowing seed in the open at the present time. Not much is gained by sowing in the open ground before the middle of February, but if the soil is found in a comparatively dry, free working condition, a week or so earlier, it is well to sow the seed. Only the hardier round-seeded varieties should be sown.

Spinach.—Rows of August-sown Spinach have already done good service, the mild autumn favouring late growth. With a change to warmer weather active growth will recommence, and this will be further promoted if soot is freely sown between the rows, and lightly stirred in with a Dutch hoe. The first favourable opportunity should be taken of sowing more seed on a rich warm border. Much the finest leaves are produced by the Victoria or Monstrous Viroflay.

Early Carrots.—It is yet too early to sow Carrot seed in the open, but those who have not the convenience of glazed frames, may yet have many early bunches of tender roots with the aid of a mild hotbed, boards, and rough coverings of some kind. Six inches of fine light soil is ample for spreading on the surface of the manure, and by sowing the Carrot seed, either Early Horn or Nantes Horn, thinly broadcast, Lettuce, Radish, and Celery seeds may accompany it. Cover lightly with fine soil, and protect with either straw or mats. Lettuce plants to be transplanted,

and Radishes pulled early, and the Celery plants to be drawn when large enough to prick into boxes, the Carrots eventually having the bed to themselves till the Vegetable Marrow plants, raised or planted in the centre, begin to ramble.

Radishes.—Market gardeners succeed in raising profitable early crops of Radishes without the aid of hotbeds or frames. A sunny open spot is chosen for the beds, and as early in February as the weather and the state of ground permit seeds are sown either broadcast or in drills, and covered with a little soil. A light covering of straw litter serves to protect from both cold wind and birds, and when the seedlings are through the ground this has to be raked off every morning, returning it again in the evening. More seeds should be sown a fortnight later.

Early Turnips.—Late-sown Turnips had good time to attain to a serviceable size, and the roots, therefore, are not so scarce this winter as anticipated. Whether they keep well or not a supply of early Turnips will be appreciated, and they also sell well. If wanted extra early sow the seed over a mild hotbed, and protect from cold winds and frosts either with glazed lights or mats. Early Milan is the best type for forcing, and also for sowing in the open. A good position for this crop is an east or south-east border made moderately rich. Sow the seed thinly in drills 1 foot apart, and protect with litter as advised in the case of Radishes.

THE BEE-KEEPER.

HOW BEES ARE DESTROYED.

IN country districts, more particularly when the apiary is near the woods, numerous bees are destroyed during the early spring months by the birds. The common house sparrows are somewhat troublesome in this respect, as they take the bees whilst on the wing. The losses from these, however, are small when compared with that pest of bee-keepers the great tit. Directly, the days begin to lengthen and the sun is gaining power, these little pests turn their attention to the bee hives. If there are no live bees visible they appropriate those that have been turned out of the hive and which have died from old age or other causes. In this respect they are useful scavengers. They are not satisfied, however, with the dead and outcast from the hives.

The birds are aware of the fact that it is only necessary to give a few successive taps at the entrance of the hive to cause the bees (should the weather be warm enough) to leave their hive. Thus they fly from one alighting board to the other, tapping with their beaks as they alight. The first bee that is visible is at once seized and taken to a neighbouring bush and dissected, the head and sting being removed, and the abdomen consumed. Only a few seconds is required for this operation, and it is surprising the number of bees a few tits will destroy in the course of an hour when the weather is favourable. It is only when there is a fall of snow and it remains on the ground for a few days that an ordinary observer will note the mischief that is being done. It is, however, not only during severe weather that this death rate is going on, as it is quite as prevalent, or even more so, during mild days, only it is not so easily detected.

DESTROYING BEE PESTS.

We are convinced that it is the large tit (*Parus major*) that is the greatest culprit. We have often trapped the blue tit (*Parus caeruleus*) on the alighting boards of the hives. But after observing their habits on many occasions we have come to the conclusion they do little harm to the bees. They will devour them quite as readily as the great tit, but we have not observed them entice the bees out. We destroy them by using a V-shaped trap, baited with bread or meat, which is a very simple and expeditious way. It is only at this season, or as long as they pay close attention to the hives and their inmates, that we trap them, as they doubtless do a great amount of good at other seasons, and their nests are not interfered with.

Mice, too, are often troublesome, but in a different manner, for it once they gain an entrance to a hive they usually take up their winter quarters there. The bees being closely clustered together in the hive, are not interfered with until the mice have consumed their stores and destroyed the combs, when they die of starvation. In some districts mice are very troublesome in this respect, and it is an advantage to always have some baited traps near the hives throughout the winter, as mice will travel a long distance for food, and they are easily caught by using similar traps to those recommended for the tits.

It is an advantage to have the entrance to the hives made not more than three-eighths of an inch in depth. This will allow ample room for the bees to pass, and the mice will not be able to gain admittance. If straw skeps are used the entrance is usually large, and the mice can thus pass in readily, unless means are taken to prevent them. If a piece of zinc is fastened over the entrance, and two or three small holes are cut at the bottom, so that the bees can pass through, all will be well.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Sweet Peas for Exhibition (B.).—We scarcely know what you mean by the "single stem system." If you mean training one plant to a stake, and these a foot or more apart, we should not deem it the best plan for an exposed position. We should prefer a richly prepared trench, nearly a foot wide—or, in other words, the ground broken up to the depth of 2 feet, and made good to that depth with sweet moist decayed manure, adding also wood ashes, as well as a handful of bonemeal, over a length of 2 yards. If the seeds are placed evenly over the trench on a layer of light soil, and covered 2 inches deep with the same kind of free soil, the surface being a couple of inches below the general ground level, and the plants appear 3 inches apart, exhibition blooms may be had by the aid of judicious applications of liquid manure when the plants are advancing in growth. We know of nothing better as supports than fresh twiggy Hazel rods, which are plentiful in some districts, and sold in bundles, both in the country and the suburbs of towns. Just as this reply is completed an article comes to hand from a successful cultivator, and it does not seem to differ materially from the advice above given.

Woodlice in Stable Manure (Gordon Road).—You wish to know what to mix with stable manure and Oak leaves to keep away woodlice, which eat up the young plants as they appear, in your propagating bed. As a rule where woodlice abound the manure and surroundings of the frame are too dry. Take care that the material of which the bed is composed is moist. A light sprinkling of guano amongst it would assist fermentation and be obnoxious to woodlice; but the surface of the bed must be well and closely covered with cocoa-nut fibre refuse or other suitable material for standing the pots on and preventing any escape of noxious gases from the bed into the frame. This covering must be kept moist, and no fissures allowed near the sides of the frame or elsewhere. If the pests still find entrance remove the pots for a few moments and give the bed a soaking with boiling water, also all round the outside of the frame in your greenhouse, and you will soon reduce the numbers of the enemy. We suspect you provide dry corners somewhere, which woodlice enjoy, and increase and multiply accordingly. We do not think they are worthy of being made so comfortable.

Apple Norfolk Bearer (D. W.).—We do not consider the variety to be Norfolk Bearer, of which the following is Dr. Hogg's description:—"Fruit, about medium size, 2½ inches wide and 2½ inches high; roundish and obtusely angular from the middle towards the crown, where it is rather narrow. Skin, smooth and shining, very much covered with lively crimson, which is marked with broken stripes and spots of darker crimson extending over one-half of the surface or wherever exposed to the sun; on the shaded side it is green, with a yellowish tinge as it ripens, and with some dots and broken streaks of light crimson where it blends with the sunny side; it is covered all over the surface with rather large russet dots, and altogether is much the same colour as Norfolk Beefeater. Eye, half open; segments, erect convergent, placed in a shallow, narrow, and plaited basin. Stamens, median; tube conical. Stalk, very short, sometimes a mere knob, or over half an inch long, slender, inserted in a narrow and not very deep cavity. Flesh, greenish, tender, crisp, with a brisk and agreeable flavour. A culinary Apple of very good quality; in use during December and January. Its great recommendation is its productiveness. I find it an excellent variety for growing in the northern districts, such as the south of Scotland, where it succeeds remarkably well." We do not know the local variety you name.

Summer Flowering Plants for Dry Shaded Border (M.).—A few are *Aconitum napellus*, *Adonis pyrenaica*, *Agrostemma coronaria*, *Anemone japonica*, *A. j. alba*, *Armeria plantaginea grandiflora*, *Campanula glomerata aggregata*, *C. g. alba*, *Digitalis gigantea*, *D. purpurea* vars., *Erodium Manescavi*, *Geranium ibericum*, *Geum coccineum fl. pl.*, *Hypericum calycinum*, (*Eurothera fruticosa* Youngi, *E. macrocarpa*, *E. taraxacifolia*, *Oxalis floribunda*, and *Sedum spectabile*. German Irises often succeed if planted, as all should be, when the soil is moist; also herbaceous *Pæonies*.

Grasses for a Lawn (Z.).—For producing a superior lawn in thoroughly clean, good, well prepared soil, the following mixture has been found to answer well. Four pounds each of *Agrostis vulgaris*, *Cynosurus cristatus*, *Festuca tenuifolia*, *Poa nemoralis*, and *Poa pratensis*. The quantities given are for a rood (¼ acre) or ½ lb. per rod of 30½ square yards. It would be better to increase than reduce the quantity where small birds are troublesome, or when a close lawn is desired very quickly. The seeds can only be sown evenly on a calm day, and it is desirable to take advantage of warm, dull, showery weather from the middle to the end of April for the operation. If the preparation of the ground is completed early in March natural weed seeds that it may contain will germinate in time for the small seedlings to be hoed up before sowing the grass seeds, and the lawn will be the cleaner. White Clover is excluded from the mixture because the leaves remain wet after dew or rain much longer than the grass does, making the surface too greasy for pleasing croquet or lawn tennis players. If Clover is desired seed should be sown separately, not mixed with the grass seeds. We have seen croquet played on ground in six weeks after the seeds were sown on 25th April. Light soil was sifted over them and warm showers followed. In this particular case half as much more seed was sown as above stated, but the quantity given answers very well when birds do not get a goodly share, as they usually do if the seeds are not placed out of their sight by a light covering of soil.

Pruning Cherry Trees (O. F.).—The Cherry, like the Apple, produces fruit mainly on spurs, the buds being, however, much smaller and several clustered together, with a growing bud in the centre. In pruning, therefore, the short stubby shoots must be left, and many of the buds on them will develop into trusses of bloom, and, all being well, Cherries will follow. Extension growths—that is, shoots that form branches, being usually of moderate strength on old trees, may be left their full length, and if thinly disposed will form spurs and give fruit in due season. When the young side shoots are a considerable length it may be necessary to shorten them to give rise to other growths at the desired points for covering the space properly with branches. Old trees usually require the old spurs thinning, cutting away the weak and long, and thus giving those nearest the wall the better advantage. They must not be very close together, but at least 6 inches apart, removing some of the least promising, if necessary. Keep the trees free from insects.

Triple Buds on Apricot Trees (Idem).—Triple buds consist of three buds at a joint of the shoot, two at the sides of a central one, which is generally a wood bud, and the others blossom buds. Spurs, which are stubby clusters of buds, must not be cut back, but if very close together some of the weaker may be entirely removed. Elongated spurs may be shortened to a growth nearer the branch from whence they proceed. This must be done very carefully and with judgment, otherwise there cannot possibly be any fruit, as growths are essential to produce it, and fresh ones do not always push from the branches when spurs are cut entirely away. The Apricot, however, produces both spurs and young shoots annually, and bears fruit on the latter as well as on the short stubby shoots or spurs. The young shoots may only be a few inches long, or they may extend several inches during the summer, but it is usual to stop these at about 6 inches of growth, or to five or six leaves of their base in July, which causes them to plump the basal buds and form blossom buds there. At the winter pruning these shoots are cut back to an inch of their base, and the buds thus left will be, or mostly are, some wood and others blossom buds. A double bud usually consists of a blossom bud at the side of a wood bud, and therefore growth is sure to issue when a shoot is cut to a double or triple bud. We do not know of any small work such as you require, but may publish illustrations that may be helpful in some future issues. A crowbar may be procured from any blacksmith. The holes for liquid manure should be made a foot or more deep, filling them repeatedly with the liquid, and afterwards closing them with rich soil and wood ashes pressed firmly down. In making the holes avoid injuring the roots, especially the large ones near the stem. The sooner the work is done after the frost has gone the better.

Eggs on Apple Twig (Medway).—The eggs are those of the lackey moth, *Bombyx neustria*, which, in the larval stage, is very destructive to the leafage of Apple and other fruit trees. From the eggs small black hairy caterpillars emerge about the beginning of May, and they spin a web over themselves for protection, which they enlarge from time to time as needed for their accommodation. The caterpillars go out to feed on the leaves and return to the web-nests. The thing is to prevent their emerging from the eggs. The rings of eggs are very hard and difficult to crush with a knife unless a hard substance be placed against the opposite side of the ring, and the back of the knife applied with considerable pressure. We have cracked and removed the bands of eggs in this way without injury to the shoots, which is often a matter of consequence, as the removal of the twigs with the rings of eggs may interfere with the progress of the tree. Where this is not material, the shoots containing the rings may be cut off and the eggs destroyed by burning. No outward application appears to act on the eggs, as they are too glassy; therefore, in the case of orchards, the larvæ may be allowed to emerge and then destroy them in the small webs, they being easily crushed with the hand,

or the trees may be sprayed with Paris green, 1 oz. to 20 gallons of water. and the caterpillars eating the leaves coated with the thin film will be poisoned by repeating the spraying at intervals of a few days if the weather is showery.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. *They should be sent on the first indication of change towards ripening.* *Dessert Pears cannot be named in a hard green state.* (S. D.).—1, Court Pendu Plat; 2, London Golden Pippin; 3, doubtful, resembles Lemon Pippin. (A. W.).—1, Bramley's Seedling; 2, Braddick's Nonpareil; 3, Court of Wick.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. M.).—1, Libonia floribunda; 2, Chimonanthus fragrans; 3, Jasminum nudiflorum. (P. P.).—1, Scelopendrium vulgare cristatum; 2, Davallia concinna; 3, Pteris tremula variegata; 4, Davallia canariensis; 5, Polystichum aculeatum; 6, Adiantum cuneatum. (B. S. D.).—1, Acacia armata; 2, Dracæna indivisa; 3, Eranthemum pulchellum. (D. J. R.).—1, Sparmannia africana; 2, Linum flavum; 3, Ceanothus rigidus; 4, Berberis Darwini. (D. S. E.).—1, Cypripedium villosum; 2, Dendrobium Wardianum; 3, Cattleya Trianae, poor form; 4, C. Trianae, good light variety.

FEEDING CATTLE FOR MEAT.

IN discussing the above subject, in this article we do not propose to include the production of veal, for the only way to produce good veal is in the natural way with the mother's milk, the calf being slaughtered at ten or twelve weeks old.

The economic production of good beef is quite another question, and in view of the severe competition from abroad, with the consequent low range of beef prices, one very difficult of solution if it is to be carried on at a profit. Every year we find the feeders of three-year-old bullocks complaining of the lack of profit, and vowing that they will in future sell off their cattle at an earlier age; but although the proportion of well-matured beasts is gradually dwindling, there are still more than enough to supply existing demands. The root of the difficulty lies in the fact that foreign beef sells at a lower price than English, and the English farmer must either improve his quality or submit to reduction in price.

The consumer asks for small joints with plenty of lean meat in proportion to the bone and fat. Now, the highly forcing process, so much advocated, of keeping young cattle in a fat condition from birth, never losing the calf-flesh, and coming to the butcher's knife at eighteen or twenty months old, has the advantage of providing the small joints; but the animals must be very carefully bred with a view to such a system, or the lean meat will not be present in the proportion required. The Shorthorn-Aberdeen Angus cross is the best animal for the above purpose.

But is it absolutely necessary to keep calves sucking until they are nine months old or more? for such has been the usual practice in forcing young beef. In the R.A.S. Journal for September, 1895, there is a short note by Sir John Thorold on the use of meatmeal for calves fed with the bucket. This meatmeal is the residue from the manufacture of Liebig's or Brand's extract, and is sent dried and ground from South America, the cost being £7 10s. per ton. It contains 16 per cent. of fat, 72 per cent. of nitrogenous matter, and phosphoric acid equal to 1.38 of phosphate of lime. Sir John scalded the meal and added it to the warm skim milk in the proportion of 1 oz. to 1 pint, and found that calves fed on it did better than those fed on skim milk and linseed porridge. A Frenchman, M. Gouin, had found this meatmeal the most successful substitute for the cream of the milk, and attributed its good qualities to the presence of phosphoric acid in a readily assimilable form.

It was found, however, that calves fed on this material did not make good veal, the meat being dark in colour, so it should only be used for store animals. Sir John Thorold found it useful for reared calves, giving it dry mixed with meal.

The successful use of meatmeal for calves is a strong argument in favour of the use of highly nitrogenous foods for young animals, a point on which most authorities are agreed.

If we are to have a well-grown, well-fleshed, fat bullock at two years old, we must see that the calf for the first twelve months has

a diet rich in nitrogen and phosphoric acid, so that it has the wherewithal to form bone and muscle.

As a large proportion of calves are born in the spring, the period of age from twelve to eighteen months will generally be spent out at grass. Good grass being a perfect natural food for growing stock, little assistance may be needed, but undecorticated cotton cake will be a safe food on grass if used in moderation. Later, as pastures run off, more cake can be given in the form of linseed added to the former ration of cotton.

The next, and a most important question is, when to bring the cattle up from grass? Do not make the mistake of keeping them out too long. Cattle for winter feeding should be in the yards by October 1st, and earlier if the pastures be poor and bare.

But we have got our animal up to the age of eighteen months, and if he has been properly treated he should be a well grown bullock, and ready to undergo the final fattening.

Nearly fifty years ago a series of very exhaustive experiments were carried out at Rothamsted with a view to testing the assimilating powers of oxen, sheep, and pigs. During these experiments it was found that the increase in animals in the fattening process depended in a much more uniform degree on the carbohydrates of the foods than on the nitrogenous portion.

The result of comparative tests showed that in the increase of weight as between an average store bullock and a fat one, the increase of fat was in proportion of 11 to 2 of other solid matters. We may, therefore, take it that we are using no misnomer when we speak of fattening bullocks; in fact it is a much more expressive term than feeding, the one in general use.

Notwithstanding the low price of starchy foods—(i.e. carbohydrates) such as Maize and Barley, few farmers can be found who believe much in their use for the fattening of cattle. When Wheat was down at 20s. per quarter in 1895, hundreds of farmers tried the use of it for cattle feeding. None have persevered with it, and even if prices were to fall to such a level again, we do not suppose they would repeat the experiment. The fact is that where there is a good supply of roots, which generally accompanies winter feeding, oil cakes are found by feeders to give most satisfaction.

Experiments with home-grown Wheat and Barley were carried out at Woburn in 1895 in the feeding of bullocks. The grain was griddled and given in conjunction with cake, other experiments being tried with cake alone. The Wheat and Barley were charged at the rate of £1 per quarter, the local value at that period. The linseed cake cost £7 per ton, and the decorticated cotton £6.

The general results of the trials went to show that the cattle gave the most increase from the mixture of cake and corn, but the difference was not a great one, and this without reckoning anything for residual manurial value. When the latter was brought into account the balance was much in favour of the cake. And this with Wheat at 20s. per quarter!

It would appear that Maize at 20s. is not a cheaper food than cotton and linseed cakes at £5 and £8 respectively, and that there is no advantage in using it except to give more variety of food and tempt the appetite during the last stages of fattening. It is at this period that a little meal sprinkled over the pulped roots and chaff encourages the animal to eat up, but if Barley can be got for anything like a reasonable price we should prefer barleymeal to ground maize.

A question in connection with cattle feeding which has engaged some attention is the advantage of cutting up straw into chaff. About ten years ago Mr. Henry F. Moore of Somerset addressed letters to 200 leading agriculturists asking them to give their experience as to—1, Chaffing; 2, Mixing; 3, Cooking; and 4, Steaming cattle foods.

The replies were very strongly in favour of chaffing straw, chiefly from motives of economy and with the view of maintaining more stock. Mixing was also strongly advocated, especially the mixing of chaffed straw and pulped roots, leaving sufficient time for fermentation to take place before use. Cooking and steaming were not looked on with so much favour, except in the case of damaged

hay or straw, which might be useless for food unless treated in such a way.

Summing up on the whole subject it appears that the young animal requires food rich in nitrogen and phosphoric acid. Linseed cake, though expensive, is too well supported by practical men to be lightly thrown aside, and if beanmeal be added in increasing quantity until the age of twelve months, then decorticated cotton cake (again in increasing quantity), the original rations remaining *in statu quo*. With the addition of a little barleymeal in the latter stages, when the beanmeal may be dropped altogether, we think that the butcher will not find much fault when the bullock comes to market, and the crops of the farm will speak silently, though eloquently, for the quality of the muck with which they have been grown.

WORK ON THE HOME FARM.

We are surely to have no winter this season, for no sooner had a couple of sharp nights last week frost-bound the roads, and set the muck carts running, than once again the wind changed, the thermometer rose, and a reversion to the previous muggy and muddy state occurred.

Last year at this time many farmers had already drilled considerable breadths of Barley and Oats. We have not yet heard of any drilling this year, for perhaps the good reason that the land is so much wetter than a year ago, and there is not the same encouragement to take advantage of a fine seedbed.

The land is certainly not yet fit for Barley sowing, but on good well drained soils Oats might be drilled with advantage on lea that has lain a sufficiently long time since ploughing. To drill now, the land should have been turned over before Christmas. Plenty of seed must be used, for the young plants will have many enemies, and four bushels will not be any too much to put on an acre. We do not ourselves care for such early sowing, but where there is a large breadth of spring corn to sow, and this is frequently the case now, Wheat has been discarded so largely, the putting in of a field or two in February helps much to relieve the pressure of spring work later on, when it always has a tendency to run into arrears.

A fair seedbed will do for Oats, as evenness of growth is not so essential for this crop as it is for Barley, and horses might be more profitably employed in drilling Oats now than in ploughing a recently trodden sheepfold with the water still in it. We like to keep the plough close up behind the sheep; but, except on the very lightest soils, it will not do to plough Turnip land in a wet state.

Wheat wants rolling, but the surface is too wet; the roller is ready in the field, and the first windy day will see us making a try with it.

Hedge plashing and scotching is now about finished, as it should be, and the men are engaged in using the best thorns for filling up gaps, and strengthening weak places in the other fences. The rail and wire fences must also be looked over, for it is not long now to spring time and spring grass.

REMARKS.

- 29th.—Continuous rain from 7.30 A.M. to 2 P.M., then dull and damp, and showery again in evening.
30th.—Damp and showery early; fair after with gleams of sun, and frequently sunny after noon.
31st.—Overcast all day.
1st.—Fair day, with some faint sun in afternoon.
2nd.—Cloudy early; frequent faint sun in morning, and brilliant afternoon and night.
3rd.—Faint sun in morning, bright in afternoon; clear night, with a slight low fog.
4th.—Fog, rather thick, till 10.30, bright sun from 11 A.M.; began to cloud about 1 P.M. and overcast later, with occasional flakes of snow.
A fine week, but with heavy rain in the early hours of the 5th, which has to be entered for the 4th. Temperature slightly below average.—G. J. SYMONS.

CHOICE FLOWER SEEDS.

- Barr's "Prize Strain" Single Begonia.—Saved from the finest colours and best formed flowers. Per packet, 1/6, 2/6, and 3/6.
- Barr's "Prize Strain" Double Begonia.—Saved from the highest quality flowers. Per packet, 2/6 and 3/6.
- Barr's "First Prize" Calceolaria.—Saved from the finest selected flowers and richest colours. Per packet, 2/6 and 3/6.
- Barr's Extra Choice Mixture Carnations.—Saved from the finest double flowers of the highest class Carnations and Picotees, per packet, 2/6.
- Barr's "First Class" Cineraria.—A select, comparatively dwarf strain, saved from largest flowers of finest form and best distinct colours. Per packet, 2/6 and 3/6.
- Barr's Superb Mixture Gloxinia.—Saved from the finest sorts. Per packet, 1/6, 2/6, and 3/6.
- Barr's "Covent Garden" Choicest Strain Primula. A very select strain, flowers of the finest colours, and of good substance. Per packet, 1/6 and 2/6.
- Barr's "Covent Garden" Primula White.—Flowers large and handsome. Per packet, 1/6 and 2/6.
- Barr's "Covent Garden" Primula Crimson-scarlet. A magnificent strain of richest colour. Per packet, 1/6 and 2/6.
- Barr's Select Blue Primula.—The finest blue variety in cultivation. Per packet, 1/6 and 2/6.

NOVELTIES

RAISED AT

WINDSOR AND OSBORNE.

It is Messrs. CARTERS' privilege to offer the following new and choice productions to the notice of gardeners and private cultivators.

BRITISH QUEEN MELON.

Raised and named by Mr. OWEN THOMAS, Supt. of the Royal Gardens, Windsor. Awarded the First-Class Certificate R.H.S. Pronounced by the Committee to be not only the very best white-flesh melon ever submitted, but the richest flavoured of any colour. Awarded the Gold Medal of the Royal Caledonian Society in association with other fruit exhibited by H.M. The Queen.

In sealed packets, price 2/6 and 3/6 each, post free.

ROYAL OSBORNE CUCUMBER.

A valuable cross between the Rochford and an improved type of Telegraph, raised and named by Mr. GEORGE NOBBS, Head Gardener to H.M. the Queen at Osborne. In our opinion it is one of the best all the year round varieties introduced in recent years.

In sealed packets, price 2/6 & 3/6 each, post free.

ILLUSTRATED CATALOGUES, POST FREE.

WE HOLD THE ENTIRE STOCK OF SEEDS
OF THESE TWO NOVELTIES.

CARTERS,

The Queen's Seedsmen.

THE BEST PEACHES.

SOME of the facile wielders of the pen have lately been indulging in interesting pleasantries concerning the best varieties of Apples. In the main they seem to agree that those of acknowledged good quality are the best everywhere (when they can be obtained), but one has to get them first. This difficulty in getting certain varieties to bear satisfactorily in some localities leads some of the happy family of Apple connoisseurs to substitute others for their own particular district. In this way much useful information has been elicited. Now, why should we not thrash out the subject as to which are the best varieties of Peaches? In this case the partiality of some varieties for certain districts is not so pronounced, as, when grown under glass, the majority behave pretty much the same everywhere, provided their cultural requirements are well attended to. Such at least is my experience.

In regard to culture on walls in the open air, growers in various districts have to look at the matter in different lights. For instance, in the Midlands and North, it is quite useless to plant any but comparatively early varieties. Warrinco, Alexander, and Hale's Early are a trio which will prove satisfactory on sunny walls almost anywhere in England. Midseason varieties, such as Royal George, Grosse Mignonne, sometimes succeed in the Midlands and North; but if we happen to get a wet August or September, they do not ripen well. On the other hand, in the South, such large late varieties as Walburton Admirable and Princess of Wales often ripen grand fruit in the open air. I do not say that they are worth eating, but they look well.

I remember, when living in Wiltshire, we invariably had grand fruits of The Princess in September, and although they were not much prized for home consumption, the London fruiterers generally paid high prices for them, for such made an imposing display in their windows, and possibly proved objects of attraction on more than one dinner table, for modern attempts at economy have become quite a science; there is on some

dinner tables a pronounced distinction between the fruit intended to be eaten and that only expected to be admired. If I were asked to name what I considered to be the six best Peaches for growing in the open air in the south and south-western counties, I should give the following: Waterloo, Early Grosse Mignonne, Dymond, Stirling Castle, Royal George, and Sea Eagle. This selection would give a good succession of fruit from July till the end of September. The constitution of each variety is good, and with high culture all are sure croppers.

Turning to Peaches grown under glass, it is necessary to make a selection suitable for early, midseason, and late houses. We have now so many sterling varieties to select from which possess both vigour, high quality, and productiveness, that there is less excuse than ever for growing sorts which do not combine all these good qualities. For early forcing, I pin my faith on Alexander, Waterloo, and Hale's Early. A house planted with these would, I think, prove a good commercial investment, for fine Peaches in May always command good prices, and without subjecting the trees to very hard forcing, these varieties may be easily ripened during that month. Stirling Castle and Royal George were formerly the favourites for early work; but when growing under the same conditions, they are fully three weeks later than Alexander. Yet there are some cultivators who still continue to plant them in the earliest house; if with the object of providing a succession the practice is sound; but when the aim is to secure abundance of fruit as early as possible, there is no justification for the practice.

For midseason houses we can make a somewhat more numerous selection, as there are many varieties so close in point of merit that it may be regarded as a matter of taste which are chosen. Stirling Castle, Royal George, and Grosse Mignonne are now old favourites which are still excellent for second early houses. They grow well, fruit abundantly, and when well done, develop fruits of fine size and attractive colour. Bellegarde, Violette Hâtive, and Noblesse form another trio of substantial worth; but were I compelled to select only three, I should name those just given, placing Royal George as the pick of the lot.

Noblesse is perhaps the most exquisite flavoured Peach grown, but it is not generally so prolific as many other varieties. Some cultivators succeed with it regularly, many other good ones do not. This seems to point to the fact that certain peculiar conditions are necessary for its welfare. Probably a considerable addition of lime or fresh lime rubble mixed with the soil when forming a border would be beneficial. Journal readers who have been successful in securing good crops annually of this fine Peach, will perhaps give the outline of their management, stating the peculiarities of the soil forming their border. My experience is that Peaches in late houses give the cultivator the best opportunities of providing fruit of the largest size, and, in good seasons, finest colour. Plenty of time can be allowed for swelling and colouring, while the protection of glass does away with the drawbacks attending open-air culture, and if the house is provided with a flow-and-return pipe, slight heat can be given at critical times when the weather is bad.

Sea Eagle, Gladstone, and Golden Eagle are three varieties which I think would be very difficult to improve upon for late houses. The first-named is a really grand Peach in regard to size, colour, and form; in flavour it does not, of course, equal Royal George or Grosse Mignonne; but then, I know of no late Peach much better than Sea Eagle in this respect. Mr. H. W. Ward, when at Longford Castle, used to exhibit grand examples at the Crystal Palace Show in September, and the superb dish staged by Mr. W. Iggulden, at Shrewsbury Show, last year, was the most handsome one at that great exhibition. Golden Eagle provides us with a brilliantly coloured variety, so distinct from all others that it always commands attention; but it is better to look at than to eat, although sometimes described as good in flavour. In the matter of flavour, Gladstone is very much better than its tempting-looking companion.

No doubt tastes differ in regard to flavour in Peaches as in most other things, and it may be that some lusty scribe will take me to task in this point, as well as others raised in these brief notes. Well, none of us will be the worse for words that carry no venom with them, and in putting me right, others may be prevented from going wrong. —H. D.

PELARGONIUMS FOR WINTER.

THERE are few, if any, plants which possess so many good qualities as the "Geranium." It is easy of culture, has an endless variety of colours, produces its flowers on long stems, and these can be had the whole year round. It is a simple matter to obtain a brilliant display during the bright and sunny months of the year, but in the cold and sunless months of winter more care and forethought are demanded. However, any trouble spent in preparing the plants is repaid, as well grown thoroughly matured specimens produce an abundance of beautiful trusses and make a gorgeous display, and I question if any other plant gives such a lavish return. Now is a good time to commence if it is decided to grow a number of these useful plants for either supplying flowers for cutting or plants for decoration in the conservatory or greenhouse.

One thing I wish to say in starting so that disappointment, which I once experienced, may be avoided by others. About seven years ago I took charge of some gardens where a good conservatory was attached to the house. I resolved to grow Zonal Pelargoniums for the purpose of having this house as bright as I possibly could. At the end of the season I had some beautiful plants bristling with trusses, but when they were placed in the conservatory in question scarcely a truss developed, but one after another they damped off till they became a perfect eyesore. The cause of this failure was simply lack of light and sunshine. That conservatory is so situated that for three months in winter it never gets a ray of sunshine; therefore, to those who have had no experience in winter blooming "Geraniums" I would say take warning from my failure, and do not attempt their culture unless you have suitable accommodation for them during winter. A house which receives a maximum of light and sunshine is the one best adapted for the plants in winter, and unless such is available I would not advise anyone to attempt to grow them.

Select sturdy cuttings of such varieties as are at hand, because in my experience one variety is as good as another for the purpose, and place them singly in thumb pots in light sandy soil. Give a thorough watering, and stand the pots on a shelf in a vinery lately started, shading from bright sunshine till they are rooted, after which they should be fully exposed to all light and air possible. As soon as the roots begin to run round the sides of the pot transfer to a larger size, keeping them close and warm for a few days till root action recommences, when they may be gradually exposed till they once more will bear exposure to full sunlight with abundance of air. At this stage they may after careful hardening be placed in cold frames, allowing plenty of room for development. In the event of cold frosty nights setting in provision should be made for protecting them with mats or other materials.

Careful and constant attention to watering and airing will be all that is requisite until they require another shift, this time into 6-inch pots, which I consider the most suitable size for flowering. As the plants will necessarily remain in these pots for a considerable period, a little extra care must be taken in their preparation. See that they are scrupulously clean both inside and outside, and the drainage so placed that there will be no danger of choking, and thus souring the soil, which is inimical to the well being of the plants. For this potting I prefer a retentive loam with a fourth part leaf mould, and sufficient rough sand to keep the compost porous; to this should be added a sprinkling of bonemeal and some approved chemical manure.

Turn the plants carefully out of their pots, avoiding injury to the tender roots, as much damage is often done by careless workmanship at this period. The plants, by having their roots broken, receive a severe check which it takes some time to overcome. Firm potting is of great importance, thus causing the plants to make short-jointed sturdy growths which will eventually produce excellent trusses. Replace, after potting, in the frames, keep close for a week or so, and then gradually expose until they can be placed outside in full sunshine upon a bed of ashes, allowing sufficient space between each plant for light and air. Pinch the points out of any shoots that have an inclination to take a lead of the rest, and thus keep the plant well balanced. Nip off all trusses as they appear till the month of September. From the time they are placed outside the daily routine work of watering should have unremitting attention, as to allow them to become too dry means death to many useful rootlets, resulting in a severe check from which it takes the plants a long time to recuperate.

When the pots become well filled with roots liquid manure should be given, commencing with weak doses, and gradually increase the strength, but be careful not to use it too strong; it is better by far to err on the side of weakness. Give it weak and give it often is sound advice. Should the plants show an inclination to grow too densely they must be tied out a little, so as to give more room for the shoots and foliage to develop.

Towards the end of September they should be placed under cover,

in as light and airy a position as can be got. Above everything, avoid overcrowding. Do not grow 100 plants, if you have only accommodation for sixty. Set the plants well up on inverted pots, so as to allow a free circulation of air amongst them. A temperature not lower than 55°, with a dry buoyant atmosphere, will secure a brilliant display throughout the dullest months of the year, at which season especially the gay trusses are highly appreciated.

Some may think I have been unnecessarily minute in details, but it is by attending strictly to what may appear trifles that success is attained. If the foregoing notes should prove helpful to someone who may be anticipating the growing of a few of these simple yet useful plants for winter blooming, then the time occupied will not have been mis-spent. It is not my intention in these notes to teach the professional, but simply to help the amateur.—ALBYN.

CULTIVATION OF LETTUCE.

THE earliest supplies of Lettuce are usually of the Cos section, this being the hardier for standing in the open ground throughout the winter from seeds sown in September. The young seedlings should be planted out in rows in October or November on good but not freshly manured ground, as a very strong and succulent growth is not suitable for withstanding extremes of cold. Damp and birds are the greatest enemies to Lettuce in winter, the former causing the leaves and centres of the plants to decay, while the winged enemies peck at the leaves to such an extent as to arrest the proper growth of the plants. Planting on firm ground in an open situation will do much to arrest the prevalence of damp, and covering the plants with wire guards effectually prevents the attacks of birds.

At this season Lettuce plants which have stood well through the winter may receive good culture in the shape of frequent hoeing of the soil during dry periods. This is largely conducive to growth, and is always beneficial. Blank spaces can be filled up by lifting and planting some fresh plants from the seed bed, selecting the strongest, and lifting carefully with balls of soil. Additional rows should be planted, and these may be placed on richer ground than recommended for the autumn planting. Place a foot apart every way if the plants are good, but closer in the rows should they be small.

In unfavourable situations for planting outdoors to stand the winter, and it is desirable to have an early supply, seed must be sown in boxes in January and February in slight heat. After germination, however, give as little heat as possible, and raise the box of seedlings close to the light in a cool frame or house. The seedlings must be thinly disposed, and when of sufficient strength be pricked out in a frame on a very gentle hotbed near the glass. They will also succeed on a bed of rich soil in a frame without the aid of a hotbed. A daily supply of air must be afforded, especially in favourable weather. It is important that the plants do not become drawn. Gradually give more air, and fully expose on every suitable occasion. Both Cos and Cabbage varieties succeed under this treatment.

Outdoor sowings may be made early in March. Select an open and rich border having a good depth of well worked soil. Pulverise the surface so as to have an even tilth of fine soil. Draw shallow drills a foot apart and half an inch deep. Sow the seeds evenly and thinly, levelling the soil again carefully. Protection must be afforded, or birds will scratch them up and make holes in the bed by dusting themselves in the soil. As soon as practicable thin the seedlings to enable them to grow sturdily, continuing to do this until left far enough apart for developing into fine plants. Water as needed, for by maintaining the soil moist growth receives no checks, which are the chief cause of premature bolting.

Keep the soil free from weeds, and the surface loose by frequent hoeing or stirring. In continued dry weather water is required frequently; but when this is likely to be the case it is highly desirable to mulch between the rows with some decayed manure, and apply water over this when a supply is necessary. The mulching ought not to be given before the plants have attained a fair size, as the cultivation attendant on thinning the plants, weeding, and loosening the soil is highly beneficial, and more conducive to growth than very early mulching, especially during a showery period.

Sowing a large quantity of seed at wide intervals is not so good a plan as making small sowings frequently during late spring and summer, for then a stock is secured in various stages of growth, rendering a continuous supply of succulent Lettuces easy of accomplishment. The thinnings from Lettuce beds may be transplanted, and the plants succeed in moist weather. When once established they grow freely. For the driest periods, however, sow the seed where the plants are to stand.

The best Cos varieties of Lettuce are Sutton's White Heart, Winter White, Paris White, and Paris Green. Of the Cabbage varieties Sutton's Favourite, Commodore Nutt, Tom Thumb, and All the Year Round are excellent.—E. D. S.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE Executive Committee meeting following the annual general meeting is usually a busy one, and that held on Monday evening last was no exception to the rule, much of the business being the nomination and election of several gentlemen to fill vacancies on the various sub-committees. Mr. Percy Waterer, the newly elected Chairman, presided, and after the minutes of the previous meeting had been read and confirmed, several of the new officers expressed their thanks for having been chosen to fulfil those positions.

On the motion of Mr. Dean (the Secretary), it was resolved that a sub-committee be appointed to consider the relations of affiliated societies with the parent society, and report thereon to the Executive Committee. It was further resolved that half this Committee consist of representatives of affiliated societies.

Mr. Crane moved that a vote be passed placing on record the high appreciation by the Committee of Mr. T. W. Sanders' services as Chairman during the past two years. Similar votes were also passed in favour of Mr. R. Ballantine and Mr. George Gordon.

It was arranged that the Society's annual outing, which this year will be to Lord Rosebery's residence at Mentmore, shall take place on Monday, July the 17th.

Replying to certain queries concerning the roll of membership, the Secretary explained that while there were in 1897 806 members, exclusive of foreign subscribers, the number for the past year was but 758. The accessions for the past year were six Fellows, eighty-five ordinary members, and ten affiliated societies, in each case the number being below that of the preceding year.

The election to fill vacancies on the Floral Committee caused by compulsory retirement under rule was then proceeded with, the result that the following gentlemen were elected—viz., Messrs. C. Gibson, W. Higgs, H. J. Jones, J. Lyne, A. Wright, C. Blick, and R. Kenyon.

The Classification Committee was also reconstituted, the Committee being almost the same as last year, with the exception that Messrs. Kenyon and Simmons occupy the places of Mr. Geo. Gordon, who resigned, and Mr. T. Bevan, who by his election to the Vice-chairmanship is now an ex-officio member.

The Schedule Sub-Committee of nine members was also elected, the following accepting a seat on that Committee:—Messrs. Davey, Moorman, Jones, Lees, Taylor, Outram, Gleeson, Nevill, and Crane.

There was some little competition for places on the Finance Committee, Messrs. Moorman, Taylor, and Crane being successful.

The Secretary then submitted the report of the Schedule Sub-Committee, the first item of which was the definition of "Amateur." A motion was also carried that miscellaneous exhibits not competing in any specified class are invited, as they afford interesting variety to an exhibition. It is not required that such be wholly grown by the exhibitor.

Various alterations in the prizes were recommended and agreed to, and among the changes is one for twelve vases of Japanese, distinct, each containing five blooms of one variety, for which the first prize is offered by Mr. H. J. Jones, and consists of a gold medal and £20. Other prizes in proportion are allotted, and each unsuccessful exhibitor will have a small silver medal.

Mr. N. Davis also offers prizes in some special classes of self-coloured varieties, and among the names of other donors are Messrs. Agate, Ray & Co., Godfrey, Webb & Sons, Hurst & Son, Daniel Bros., and Fidler.

The Chairman, Mr. P. Waterer, also offers the sum of £5 for the best essay on the rust, the same to consist of not more than 2000 words, to be type-written, and sent in to the Secretary by the 1st October. Messrs. T. W. Sanders, Massie, and Waterer will adjudicate upon the papers. For further particulars as to this and other matter contained in the new schedule, reference must be made to it when published.

On the motion of Mr. Bevan it was resolved that the silver-gilt medal be offered to the French N.C.S. for competition at the Lyons Chrysanthemum Show next November.

New members were elected, and local societies at Ipswich and Buxton were admitted in affiliation. A vote of thanks to the new Chairman brought the proceedings to a close.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE first ordinary meeting of the present session was held on the evening of the 8th inst., when the usual business transactions of the

Society were dispensed. Mr. John Haigh gave an essay upon bulb culture in the open ground, referring only to those bulbs suitable for outdoor cultivation in this district. Suitable varieties were enumerated, the bulk of them having been grown in the neighbourhood. Pots of Tulips were exhibited by the professional members, the result being that the prizewinners were Messrs. J. Dixon, Mr. Morton, and C. Scott, in the order of their names. The amateurs' exhibits were pot plants in bloom, when Mr. T. Lygo secured first and Mr. W. Donaldson second prize. Messrs. W. Artindale & Son of the Sharrow Vale Nursery exhibited (not for competition) a large collection of Tulips, principally La Reine, Thomas Moore, Rose Gris-de-Lin, and double and single Duc Van Thol, for which the Society's certificate was awarded. They also exhibited some beautiful Primulas. The meeting was presided over by Mr. John G. Newsham.

MAIDENHEAD CHRYSANTHEMUM SOCIETY.

THE second meeting of the above Society took place on the 9th, when Mr. Jas. Hudson, V.M.H., read a paper on "Orchard House Fruit Trees." There was a good attendance of members considering the very rough weather. The essayist dealt with the subject from every point of view, and also had plans of the orchard houses at Acton for the inspection of members. He grows nearly 1000 trees in pots, consisting of Peaches, Nectarines, Cherries, Plums, Apples, Pears, and Figs. After the trees are taken out of the houses, Melons are grown on hotbeds in some houses, Tomatoes in others, and Chrysanthemums and late Figs are put in after the Melons and Tomatoes are over, making it possible to obtain three crops in the year. At the close of the lecture a vote of thanks was proposed by Mr. Haylor, and seconded by Mr. Fulford. Mr. Richardson took the chair, and at the close of the meeting several new members were enrolled.—W. M.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—FEBRUARY 14TH.

THE exhibition at the Drill Hall on Tuesday last was one of the finest that we have seen for some time. The exhibits were so numerous that almost the whole of the tables were fully occupied with Orchids, miscellaneous plants and fruit. Apples and Pears were well shown, while Orchids were seen in bulk, and were characterised also by quality. The Floral Committee had many groups to examine, and some of them particularly were highly meritorious.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Messrs. G. Bunyard, J. Cheal, J. H. Veitch, J. Basham, G. Norman, W. H. Divers, A. F. Barron, S. Mortimer, A. Dean, C. Herrin, W. Bates, G. T. Miles, G. Wythes, H. Balderson, F. Q. Lane, J. Smith, J. Willard, W. Poupard, and the Rev. W. Wilks.

Messrs. G. Bunyard & Co., Maidstone, staged a grand collection of Apples. The individual dishes were equal to any seen in October, every variety being sound and in perfect condition. There were about sixty dishes, in as many varieties. It is almost a pity to individualise where all were so good, but Striped Beefing, Blenheim Orange, Warner's King, Annie Elizabeth, Belle de Pontoise, Stone's, King of Tompkin's County, Beauty of Kent, Allington Pippin, Bismarck, Gloria Mundi, Cox's Orange Pippin, Lord Derby, Loddington Pearmain, Sanspareil, and Lane's Prince Albert were equal to any seen at the Great Fruit Show.

Dr. R. Sisley, Ockford, Godalming, also sent a small collection of Apples, which were rather small, and many varieties, past their best. Messrs. J. Cheal & Sons, Crawley, exhibited an extensive display of Apples in a well-preserved condition. The best dishes were Lord Derby, Newton Wonder, Alfriston, Atalanta, King of Pippins, High Cannons, Bismarck, Beauty of Kent, and Bramley's Seedling.

Mr. J. Miller, gardener to Lord Foley, staged a fine basket of Mushrooms of the button type. Mr. G. Wythes, V.M.H., gardener to the Duke of Northumberland, exhibited fruit of Vanilla planifolia growing on a large stem of the plant.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. G. Nicholson, H. B. May, J. H. Fitt, R. Dean, E. Molyneux, J. Hudson, G. Gordon, J. Walker, C. E. Pearson, J. D. Pawle, C. Jeffries, J. W. Barr, R. W. Kerr, E. H. Jenkins, C. R. Fielder, T. W. Sanders, G. Beckett, E. T. Cook, D. B. Crane, H. J. Cutbush, H. S. Leonard, C. E. Shea, C. Blick, and G. Paul.

Messrs. H. Cannell & Sons staged a large exhibit of Primulas, consisting of 150 plants, to illustrate the decorative value of the plant. They were growing in 60-pots, and each plant carried several heads of bloom. The most noteworthy were Mrs. R. W. Cannell, white with dark foliage; Purple Star, Harlequin, a pretty, striped form; Lady Whitehead, a good white; Lady Emily Dyke, very floriferous, white; and Princess, a white Fern-leaved variety. Messrs. Barr & Sons, Covent Garden, exhibited a charming display of Primulas, Narcissi, Chionodoxa sardensis, hardy Cyclamen, and other flowers. The Daffodils were Golden Spur and maximus in the yellow trumpet class; white trumpets were represented by Princess Ida, W. P. Milner, and Mrs. Thompson, with numbers of N. minimus and N. cyclamineus.

Mr. H. B. May, Upper Edmonton, staged some remarkably fine plants of Begonia Gloire de Lorraine, arranged with well-grown plants of Adiantum Farleyense. Messrs. Collins Bros., Hampton, showed an extensive display of market Tulips. The bunches were large, and the

flowers in great variety. The most conspicuous were Grand Duke, Rosine, La Reine, Prince of Austria, Thomas Moore, Yellow Prince, Chrysolora, Scarlet Duc Van Thol, and Couronne d'Or.

Messrs. J. Veitch & Sons, Chelsea, exhibited a charming bank of single and double Primulas in a variety of colours. The best were Magnum Bonum, Gigantic Salmon, Chelsea White, Gigantic Blue, a very fine form; Gigantic White, Gigantic Scarlet, and Gigantic Rose in the single section, while the double mauve, salmon, scarlet, and blue were all exceedingly good. The same firm also contributed a tray of Rhododendron hybrids, comprising good forms of Minerva, Diadem, Conqueror, Hercules, Primrose, and Mrs. Heale. Mr. John May, St. Margarets, Twickenham, staged a grand display of Cyclamen, in 48-pots. The plants were very fine, with clean well-developed foliage, and carrying a quantity of excellent flowers in a good variety of colours.

Messrs. Wm. Paul & Son, Waltham Cross, contributed a superb display of Camellias in pots; also eight boxes of cut blooms. The plants in pots were well flowered, in fact they were literally covered with flowers. The old alba plena comprised the bulk of the display. Marchioness of Exeter, corallina, Exquisite, conspicua, and Rosy Morn were well represented by good specimen plants. The boxes of cut blooms contained excellent examples of L'Avenir, Countess of Derby, Reine des Fleurs, Lady Hume's Blush, Beauty of Waltham, and Princess Charlotte.

Messrs. Paul & Son, Cheshunt, exhibited plants of Calceolaria Burbidgei, the extraordinary Strelitzia regina with a fine spike of bloom, Hamamelis zuccarenia with its curious blooms, and a bunch of well coloured Marechal Niel Roses. Mr. W. Allan, gardener to Lord Suffield, Gunton Park, showed a group of Lachenalia Nelsoni; the plants were beautifully furnished with flowers; also a basket of Cannas with variegated foliage.

Messrs. Sander & Co., St. Albans, staged a table of new plants, including some fine specimens of Acalypha hispida (Sanderi), A. Godseffiana in small pots, Dracaenas Sanderiana and Godseffiana; also a very fine form of Hæmanthus cinnabarinus var. superba.

Mr. F. Miller, 110, Fulham Road, contributed an effective display of floral decorations, comprising baskets of double Daffodils and various other forms of Narcissi, with Freesias, Spiræas, Lily of the Valley, and other spring flowers. Messrs. R. Wallace & Co., Colchester, arranged a small but interesting display of spring flowers, chiefly Irises verticillata, Bakeriana, Histrio, Histrioides, and Danfordia (a miniature yellow from Asia Minor), the white Chionodoxa Lucilia alba, and a gigantic Snowdrop, Galanthus Elwesi Whitalli. Mr. T. S. Ware, Ltd., Tottenham, exhibited a group of spring flowering plants, consisting of Narcissi in various forms, Crocus Sieberi, Hellebores, Orchis fusca, hardy Cyclamens, a pan of Leucoicum carpatum, also a pan of Gaultheria procumbens.

Messrs. J. Hill & Son, Lower Edmonton, staged a very fine exhibit of Ferns in pots and baskets. The collection included baskets of Pteris internata, P. nemoralis variegata, P. ensiformis Victoriae, and P. palmata, with good specimens of Davallia dissecta, Gymnogramma Veitchi, and Woodwardia radicans; also a group of a new Fern, Asplenium Hilli, a seedling from A. Belangeri x A. bifforme. Mr. Chas. Turner, Slough, sent a group of Malmesbury Carnations Princess May, the red flowering form. Mr. Jas. Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury House, staged a plant of Lourya campanulata in flower, which presented a very curious appearance.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshaw, J. Colman, J. G. Fowler, H. Little, A. Outram, H. J. Chapman, W. H. Young, H. T. Pitt, E. Ashworth, W. H. Protheroe, W. Cobb, C. Winn, J. Douglas, S. Courtauld, E. Hill, and H. Ballantine.

A small group of Orchids was arranged by C. H. Feiling, Esq., Southgate House, Southgate. It comprised Dendrobium nobile, D. Wardianum, with Odontoglossums, Oncidiums, and such Cyripediums as Boxalli, Williamsi, Euryades, Harrisianum nigrum, and Measuresianum. The plants were clean and well flowered. Messrs. B. S. Williams & Son, Upper Holloway, were represented by a large collection of Orchids interspersed with Palms, Ferns, Oranges, Aralias, and other foliage plants. Amongst the most conspicuous of the Orchids were Cyripediums Sallieri, superbiens, nitens superbum, villosum, and Fitchianum; Dendrobiums in variety, Cœlogyne cristata, Odontoglossum crispum, O. Rossi, Calanthes, Cattleyas, and others. Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, contributed a most interesting exhibit of well diversified Orchids. The plants were splendidly grown and carried numerous flowers. Amongst others were Odontoglossum pulchellum, O. Andersonianum; Cyripediums Conco-Lawre, Calypso Oakwood variety, Lathamianum, Calypso var. villosum giganteum, Lawrebel, villosum, Leeanum, and others; Dendrobiums melanodiscus, burfordiense, Thalia, Juno, Leechianum, nobile Burford variety, and melanodiscus Aurora; Masdevallia polysticha, M. Hincksiana, M. ignea, M. irrorata, M. i. Schröderiana; Lælia anceps Veitchi in superb form, Epidendrum Endriesi, and several others.

Messrs. J. Veitch & Sons, Ltd., Royal Exotic Nursery, Chelsea, arranged a number of charming Orchids in a very effective style. Cattleya Trianae was there in varying forms, with Dendrobiums infundibulum, Dulce, splendissimum, Cordelia, Euosmum virginale and Domini, Odontoglossums Wilckeanum and Andersonianum, Oncidium cheiroporum, several Cyripediums, and others. Phalaenopses formed the bulk of the group from Messrs. H. Low & Co., Bush Hill Park, and splendidly they were shown. There were also Cyripediums, Cattleyas, and Angræcum sesquipedale. Mr. F. Knight, Thundersley, Essex, showed Cattleya Trianae in variety, with Cœlogyne cristata.

Mr. Whiffen, gardener to F. Bradshaw, Esq., Southgate, sent a

number of Orchids, in which *Odontoglossums* and *Cattleyas* were most prominent. There were also *Cymbidium eburneum* and *Lycaste Skinneri* Enchantress. Small exhibits of Orchids were in abundance, and included plants from Messrs. H. J. Elwes, G. Moore, W. H. Young, de Barri Crawshay, Fisher, Son, & Sibray, F. Sander & Co., and E. Ashworth, with Sir W. J. Denton and others.

AWARDS.—Fruit Committee: Gold medal to Messrs. G. Bunyard & Co., and silver Knightian medals to Mr. G. Wythes and to Messrs. J. Cheal and Son. Floral Committee: silver-gilt Flora medal to Messrs. W. Paul & Son: silver Flora medal to Messrs. H. Cannell & Sons; silver-gilt Banksian medals to Messrs. Hill & Son and J. May, and silver Banksian medals to Messrs. H. B. May, J. Veitch & Sons, Ltd., and Collins Bros. & Gabriel.

CERTIFICATES AND AWARDS OF MERIT.

Apple Sanspareil (G. Bunyard & Co.).—A handsome Apple rather over medium size. It is decidedly conical, narrowing towards the apex. The sides indistinct angles, becoming more pronounced at the crown. The very small eye is deeply set in a narrow basin. The stalk is about half an inch long, and is set in a funnel-shaped cavity, which is lined with russet. The colour is a uniform clear yellow, flushed and splashed with red on the side next the sun (first-class certificate).

Cattleya Trianae Amy Wigan (W. H. Young).—A lovely variety. The sepals and petals are deep purple rose with a flush of crimson on the sepals. The fimbriated lip is deep crimson with a suffusion of purple (first-class certificate).

Cypripedium Orion (J. Veitch & Sons).—A chastely beautiful hybrid from *C. concolor* and *C. insignis*. The ground colour is cream throughout, deeper in the dorsal sepal, and flushed with rose in the petals. The spots over all are crimson, but larger on the dorsal sepal and minute on the pouch (award of merit).

Hippeastrum Sir William (Royal Gardens, Kew).—A superb variety, with large rich deep crimson flowers (award of merit).

Laelio-Cattleya warnhamensis Hypatia (Charlesworth & Co.).—This is very handsome. The rich orange of the sepals and petals, and the crimson maroon of the lip is most intense (award of merit).

Masdevallia falcata (W. H. White).—A fairly well-known form with orange coloured flowers, darker towards the margins (award of merit).

Narcissus Trimon (Barr & Sons).—A small flowered variety after the style of *monophyllus*. The colour is pale cream (award of merit).

Phaio-Calanthe Niobe (J. Veitch & Sons).—This bigeneric hybrid results from a cross between *Phaius grandifolius* and *Calanthe gigas*, and partakes of the character of both, but mainly perhaps of the former. The sepals and petals are rose, as is the outer portion of the lip; the throat is primrose (award of merit).

Phalanopsis Mrs. Jas. H. Veitch (J. Veitch & Sons).—This hybrid resulted from a cross between *P. Luddemanniana* and *P. Sanderiana*. The sepals and petals are yellow with a tinge of green and numerous crimson brown spots. The lip is white on the front lobe with yellow in the throat, and crimson markings (award of merit).

Rhubarb The Sutton (M. Butler).—A fine variety with long stems of good thickness, and excellent colour (award of merit).

STAPELIA PATULA.

THE reason is not far to seek why the members of this large and strange genus are so little cultivated by general collectors of plants. Known for a good reason as Carrion Flowers, the characteristic foetid smell of the flowers, large and even handsome as some of them are, is not agreeable, to say the least, to many persons. The plants are interesting and remarkable from several points of view, and deserve greater attention from the hands of those not too fastidious in scents. Belonging to a strange order *Asclepiadaceæ*, which includes the curious *Dischidia Rafflesiana*, the *Asclepias*, and others, they are far from the least curious of these anomalous species.

There are reasons for thinking that though the *Stapelias* have a considerable range in South Africa, they are gradually dying out. The natives eat them as food, and the introduced ruminants as sheep and goats, which are being bred in increased numbers, also feed off them. These causes have led to their proximate extermination near towns, and as the country becomes settled the same causes will act more largely. The seed being set exclusively by the agency of insects, any disturbance in the balance of Nature is likely to affect them prejudicially. But, apart from such eventualities, the curious succulent leafless stems, the flowers, with their curious and diverse coronal appendages, the hairs frequently found upon the disk and margins of the corolla, the marblings and generally lurid colouring of the same organ, separate them from the general run of succulent plants. There are no difficulties in growing them, either from seed or cuttings. A well-drained compost of sandy loam, with broken-up brick rubbish suit them. The seeds are singularly retentive of life, and germinate in from one to three days, retaining their vitality (many of them) for eight or ten years. If the plants are kept dry in the winter a short snap of frost is not harmful, and by placing them near the glass in the full sunshine they may be grown without artificial heat.

About sixty species are now included in the genus of *Stapelia*, though Mr. N. E. Brown, who has given much attention to South African plants, is of opinion that these are, many of them, only local forms or strains, or natural hybrids, and possibly only of an evanescent nature. Many of the so-called species are so connected by intermediate forms, blendings, and interminglings of characters, that the classification is attended with unusual difficulties, and this is doubtless the reason why the few botanists who have given attention to the genus vary so much in the species included. Only five were known to Linnæus, who gave the generic name after an Amsterdam physician. Masson, who was a collector for the then royal collection at Kew, published in 1796 drawings of forty-one species.

FIG. 25.—STAPELIA PATULA.

Jacquin in 1806, and Haworth in 1812, added more new species. About the same time the botanist Robert Brown broke up the genus into four, but later botanists as Decaisne, Bentham, and Hooker have brought most of them back into the genus *Stapelia*.

Stapelia patula (fig. 25) was named in 1809 by Willdenow. Three vicinities in South Africa within forty miles of each other in the neighbourhood of Mitchell's Pass are given as its habitat. Like so many of the *Stapelias* it is subject to considerable variations, and these run into by close gradations, forms described under other specific names, that Mr. Brown finds it impossible to give a set of characters which shall specifically separate them. *S. comata*, *S. unguipetala*, and *S. depressa*, according to this botanist, are possibly only forms of *S. patula*. The flower in the engraving, sketched when the divisions of the corolla had become reflexed, does not give the stellate appearance characteristic of the earlier stage. The mass of hairs thrown off by the margins and reflexed, are a dull pink in colour, the surface of the corolla is marbled in fleshy purples.

RECENT WEATHER IN LONDON.—Rain has fallen more or less each day since last Saturday, and the wind, on more than one night, has blown with terrific force. At intervals there have been bright gleams of sunshine, but on no occasion have they lasted very long. The morning of Tuesday was very wet, and showers fell afterwards, particularly in the evening. On Wednesday, at the time of going to press, it was fine.

— WEATHER IN THE NORTH.—The morning of the 7th showed 4° of frost. Thaw set in in the afternoon, and three very wet days followed. Saturday was fine, with heavy rain in the evening, and Sunday was, especially in the afternoon, fresh and springlike. Throughout almost all Monday rain was persistent and heavy, with a coldish wind from the east.—B. D., *S. Perthshire*.

— PRESENTATION TO THE AVIARY IN STANLEY PARK.—The inhabitants of the City of Liverpool in this poorer part will be glad to learn that Mr. William Cross, the celebrated naturalist of Liverpool, has offered to stock at his own expense the aviary presented to the city by Councillor J. R. Grant. This, with the handsome new Palm house presented by Mr. Yates Thompson, and which is being built by the well known firm of Messrs. Mackenzie & Moneur of London and Edinburgh, should stir up a great interest amongst the working classes, and make them appreciate the object lessons of nature and art brought close to their doors.—R.

— POTATOES AND LIME.—In talking with a gardening friend a short time ago, the subject in some way turned to the "noble tuber." "Oh," said my friend, "taters do no good in our garden, they grow so much top and come so badly at the root." Knowing what an old garden it was, I said, "You should use some lime." "Lime," said he, "what-ever's the good of lime for 'taters'! I don't believe in these new-fangled notions." I endeavoured to explain that the idea was not at all new—in truth, I had read in the *Journal* that the use of lime was known to the old Romans. "Ah," said my neighbour, "I suppose they did a goodish bit of building at one time." I hurriedly changed the subject.—SUBMERGED.

— READING GARDENERS' ASSOCIATION.—A very interesting lecture on "Destructive and Injurious Sawflies" was given on Monday evening last, the 13th inst., before the members of the above Association by Mr. P. H. Foulkes, B.Sc., Edin., of the Reading College. In introducing the subject, the lecturer said that Sawflies belonged to the order Hymenoptera, which included all those insects that had wings of a membranous character, and that this particular order was also divided into various classes. The Sawflies touched upon were the Apple, Gooseberry and Currant, Cherry and Pear, and the Turnip. Their time of appearing, method of attack, the best means to take for their prevention or destruction, and the various stages of growth were fully dealt with, the latter more particularly so, by the aid of several illustrations shown by the limelight. Many questions were asked, and ably answered, and an interesting discussion took place. A vote of thanks to Mr. Foulkes brought the meeting to a close.

— A FRIEND.—The following may be of interest to those who regard the toad as the gardener's friend. For some time past we have kept a toad in our stove, chiefly to assist in keeping down woodlice, and this it has done we are assured. But we are indebted to our "friend" in another way. In all our houses we are troubled, more or less, with what I take to be a minute species of ant, which feeds on the excrement of mealy bug and scale; various attempts to exterminate this little pest have proved fruitless. One night recently, while searching for a slug that had been making free with some Orchid blooms, I came across the toad, stationed at the base of an iron rod which supports the stem of a Stephanotis, and watching for a short time I noticed the toad thrust out its tongue repeatedly towards the rod. Curious to know the meaning of this I began to scrutinise, and then saw that the toad was licking off the ants, which were continually passing up and down the rod from the Stephanotis. The toad was left undisturbed, and the following morning was found at his post. Those who are acquainted with this ant may imagine the quantity a toad would consume in one night, and to see it feeding would, I think, assure the most credulous person that he is indeed a friend.—PARVO.

— EATERS OF THE IVY.—I have lately come to the conclusion that many more caterpillars than naturalists are aware of feed upon the Ivy during autumn and winter; they secrete themselves amongst its leaves and twigs to hibernate, and then occasionally nibble the younger portions of the plants; also, I have observed that when growing upon banks Ivy is at times considerably eaten by snails and slugs, though we should not have supposed it would have been food to their taste.—ENTOMOLOGIST.

— THREE GOOD NEW ANNUALS.—In looking through the enormous number of annuals in cultivation it would almost appear as if we had sufficient for all purposes, but improved types continue to appear, and three decidedly above average merit for beds are now mentioned. *Matriearia eximia* Golden Ball is a gem, and must be seen to be appreciated. It grows into a compact bush of about a foot high, and almost the same in diameter. The double quilled flowers are an intense golden yellow colour; in fact a Pompon Chrysanthemum in miniature would almost describe it. For a long border plant or for bedding it is admirable. Candytuft Rose Cardinal will be found a welcome addition to this popular family, the distinct rich rose cardinal colour showing to great advantage. Candytuft Giant Hyacinth-flowered white, is the third. The spikes of bloom sometimes measure over 7 inches in length. For cut flowers it will be found of great benefit, whilst it will quite supersede the old white variety for bedding.—R. P. R.

— TECHNICAL HORTICULTURE.—When at Kingston, on the 11th instant, was opened an exhibition of the work performed by students in the various County Council classes for plumbing, wood carving, modelling, painting, and other of the semi-mechanical arts, I could but wish it were possible to create, in the same way, an exhibition of what is being taught and accomplished in horticulture in the County of Surrey also. But the operations of gardening have to be conducted on the soil, and it is not practicable to take to any centre a few scores of the best boys' gardens, much less of allotments and cottage gardens, and show them as products of technical instruction. Indeed, it too frequently happens that all the training thus exemplified is so situated that its practical effects are seen by few but the actual workers, hence relatively few persons know what is being accomplished. This is specially the case with cottage gardens, many of the best of which lie remote from populous districts, whilst even groups of allotments in rural localities are seldom seen by visitors. In some few places, notably at Richmond and Surbiton, a walk round the allotments on Sundays is common recreation. That is not the rule in country districts. Very few persons, again, visit the boys' gardens, as these are usually found in enclosed grounds. But the cottager and the allotment holder, and here and there where the local people offer encouragement, the boys from their school gardens, have opportunities to display publicly at their local shows examples of their produce, the result of technical training. No doubt, could a great county exhibition of such produce be held in various county centres annually, the display would be a remarkable one, and would afford effective evidence of the value of the technical teaching in gardening which is furnished.—A. D.

— SHERBORNE GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—At the last meeting there was a large attendance, and a splendid show of dessert and kitchen Apples. An excellent address was given by Mr. Crook, of Forde Abbey Gardens, on "Profitable Fruit Culture." Before dealing with his subject he made reference to the death of the late Mr. W. G. Pragnell, the head gardener at Sherborne Castle, and spoke in very high terms of the deceased, whose acquaintance he had enjoyed for about thirty years. He also remarked that his successor was also an old friend of his, and held a high position in the gardening world. Referring to fruit culture, he asserted that this country was increasing in its demands for good fruit and vegetables, and for anyone who cared to embark in the cultivation there was a good opening. He maintained that Cox's Orange Pippin, the qualities of which it took the English thirty years to recognise, had been pronounced by expert judges to be the best Apple of the day, and a man who understood his business would not sell it for less than 2s. per dozen. The West of England was one of the best parts in this country to grow fruit; but what did they find in their orchards? Miserable relics. If they planted Apples like the Cox's Orange Pippin they would make money instead of sending it out to America, Tasmania, and California. He had seen Blenheim Oranges in the Yeovil Market for which 3d. per pound was asked, and he had gathered 110 lbs. of fruit off of a Lane's Prince Albert, which was only 7 feet high and 7 feet in diameter; and another tree, Seaton House, which was introduced from Scotland, and bears early, would pay to grow. Mr. Crook also gave hints on storage, and concluded a very interesting and practical address, amidst applause.

Rain fell on six days, Monday's being very cold and mixed with snow and sleet; wind changing from south-east to south-west. On Friday the sun was very warm, the thermometer registering 64° in the shade.

— **WEATHER AT CHISWICK.**—We are pleased to learn that what might be termed an ancient feature of the historical gardens of the Royal Horticultural Society has been resuscitated. For many years Chiswick was a meteorological station, and the reports were acceptable to the gardening community. Great care has been taken in the equipment of the resumed section and in the accuracy of the instruments provided under the personal supervision of Mr. Edward Mawley, late President of the Royal Meteorological Society. As the Superintendent of the Gardens is an old and careful observer the tabulated returns may be relied on as correct. We are very much obliged to the Royal Horticultural Society for supplying them for the information of our readers.

— **FEBRUARY WEATHER—A DIFFERENCE.**—On Thursday last, the 9th inst., the thermometer in London rose to a maximum of 58°, or 12° above the average for the time of year. According to submarine telegraph the day's record in New York was 2° below zero, and at Chicago 30° below zero. The next day, the 10th inst. (last Friday) the report from New York was 6° below zero. At Chiswick on the same day, as will be seen by the above returns, the shade thermometer registered perhaps the warmest 10th of February recorded there, as it was at Camden Town for forty years. We are inclined to prefer the February weather of the Old Country—this year, at least; but four years ago (February 8th, 1895) the thermometer in London fell to within 7° of zero. At Belvoir on the same day the register was 3° below zero. We may add that the cold was greater on several days last June, also on three in July, the 6th, 10th, and 29th, than on the warm February Friday indicated.

— **THE MILD AND WET WEATHER.**—Only a short time since we were rejoicing over the touch of cold weather which for a few days prevailed, and which we hoped would serve to keep vegetation in check. But it has been speedily succeeded by such a turn of soft mild weather, that the temperature is more that of May than of February; thus all our earlier anticipations are overthrown, and the sudden warmth following upon the short cold touch, which gave the lovers of skating an illusory hope, and enabled some needful ice to be housed, so sudden a reaction rendered matters worse rather than better. There is no checking all sorts of things now, and we may well look with anxiety to the ultimate outcome of the variable weather. February has at length justified its old appellation of "fill-dyke," for rivers, streams, brooks, and ditches have of late been full to overflowing.—OBSERVER.

— **HESSLE GARDENERS' SOCIETY.**—At a meeting of the above Society held on the 7th inst., Mr. F. Mason presiding, Mr. Lambert of the Burton Constable Nurseries read a paper on "Fruits for Exhibition," dealing concisely with all the different kinds which are to be found on the exhibition tables. He gave a list of varieties which he had found most useful in his own locality, both for early and late shows. By special request of the members he also gave the members his views respecting the different stocks used for grafting and budding. There was an excellent discussion, which was entered into with much zest and enthusiasm by the members present. There were several questions put to the essayist which were answered in an able manner. The usual vote of thanks brought a very instructive meeting to a close.—J. T. B., Hesse.

— **ASPARAGUS NOTES.**—On page 102 "W. S., Wills," speaks of the value to young gardeners of an article on the above subject by Mr. Shalford in a previous issue. In one establishment, in which I served as a junior, Asparagus refused to succeed; but I think if the method of disposing of the garden refuse, and planting on the surface (as recommended by "W. S., Wills") had been adopted, the difficulty to a certain extent might have been overcome. The culture of vegetables is, I fear, at times neglected by our young men, whose minds have been in numerous instances filled with temperatures, ventilation, and other matters connected with work under glass; and while in no way wishing to deprecate the value of all such things, the time is sure to come to most of these embryo gardeners, when a thorough knowledge of outdoor work will be valued.—KITCHEN GARDENER.

— **POTTING TOMATOES.**—I can endorse the remarks of "Practice" (page 101) regarding the advantage of potting Tomatoes deeply. It is the only way, and placing them in a light, warm, airy position, of keeping the young plants sturdy. From the very first, when the seedlings are ready to be removed from the pots or pans in which they have germinated, they show this tendency to emit roots from the stems. The stronger the seedlings are the more roots appear to be ready to develop. Therefore it is not only with spindled plants from autumn cuttings that the practice of deep potting should be adopted, but also with spring raised seedlings. Most growers when finally placing Tomatoes in their fruiting pots sink them very low down, so that soil may be added round the stems from time to time and new series of roots formed. These strengthen the plants and cause them to be fruitful by the additional vigour imparted. This important fact is well known to all experienced Tomato growers. Still it may not be clear to some of the younger growers. Any who have not proved the value of the reliable practice indicated should try the suggestion of your correspondent, who does well to call attention to the matter. Potting seedlings to the seed leaves is also alluded to by Mr. Abbey on page 91.—E. D. S.

— **SCIADOPITYS VERTICILLATA.**—One occasionally sees and reads of very fine specimens of the Umbrella Pine, as it is commonly called; but experience proves that this Conifer will not flourish everywhere. Twenty years since two trees of it were planted in the ordinary soil of this garden, no special preparation being made beforehand. The staple is a strong loam on the surface—in fact, it is stiffer than would commonly be known as loam. The subsoil is not actually clay, but it is a close approach to it. The surface soil is highly impregnated with chalk, much of this having been employed in years gone by for surface dressing. The plants alluded to lived it is true, but made no progress for several years, so they were lifted and replanted in a compost of a sandy character. Instead of improving, they dwindled distinctly. Thinking to put new life into them I transplanted them to another part of the garden, first preparing the stations carefully by removing the whole of the soil 2 feet deep. At the bottom of each hole a layer of drainage was put and a compost of peat, leaf mould, decayed vegetable refuse, and turf. The trees were carefully watered when necessary—in fact, no pains whatever were spared to induce the trees to grow, but after fifteen years trial both turned yellow, and were ultimately burnt.—E. MOLYNEUX.

— **ILLICIT COMMISSIONS.**—In concluding a speech of, for him, unusual gravity, delivered at Kingston on Saturday last, the Lord Chief Justice of England stated that so much did he feel the mischief done to British trade and investments through the giving of what he described as illicit commissions, that he purposed shortly to bring in a Bill in the House of Lords making the granting of these commissions illegal. What the noble Lord may mean by illicit commissions was not made clear, although it is very probable that he had in his mind some recent revelations of a very foul financial nature. But I have been wondering whether it is probable such a Bill would in any way meet certain cases which seem to have cropped up in connection with the horticultural trade. The subject is one very difficult to refer to; but whilst there has been much correspondence and no end of grave complaints made in certain directions concerning commissions, there does not appear to be any great objection offered to the payment of such as may be moderate—that is, about 5 per cent., and it may be advisable to do so for inducing early settlements. But what seems to be complained of is, that in the keen race of competition, some traders offer, through their circular, or by private letters, or through agents, to give 10, 15, and even 20 per cent. commission. Most certainly such commissions cannot be properly offered, and seeing that their object is to tempt the largest possible orders, and to take away honest traders' customers, such offers seem to me to come under Lord Russell's term illicit.—D.

— "PHYSIOGRAPHY."—I am pleased to note that "Erica," of "The Young Gardeners' Domain" (page 114), has had the good fortune to study the above grand work by the eminent Professor Huxley. It is one of the most wonderful scientific works I have yet read, setting out as it does in understandable language the marvellous forces at work in the whole universe, and especially in our own land. That portion which treats of geology is perhaps the most interesting and useful to gardeners, as it teems with information which one may daily turn to practical account. "Physiography" is a book to read once and study ever after.—H. D.

— A COMMON ERROR—"Observer," page 86, does well to draw the attention of readers to the subject of fixing the wires for the training of Vines, Roses, and other plants too closely to the glass. No crop will exhibit the effect of this practice more quickly than Melons and Cucumbers growing in a house where the leaves are nearly touching the glass. Seldom, indeed, can either pass through a season of growth without loss of many of the leaves by scorching, owing to lack of air in sufficient quantity to dissipate the condensed moisture that collects on the upper surface of the leaves. The wires in the Cucumber and Melon houses here were fixed 17 inches from the glass. In practice, however, even this distance is too near for vigorous-growing varieties. Foliage of any kind, whether that of fruit trees or plants, is more liable to a loss of colouring matter—chlorophyll—when growing near to the glass.—E. M., *Sussexmore*.

— A STAG IN A GARDEN.—The proverbial bull in a china shop is the metaphorical creator of the proverbial smash. A visitor of a somewhat similar nature was that unfortunate stag which, driven by the Royal buckhounds recently to seek a harbour of refuge from the baying dogs, looked to find it in the gardens of the Countess de Morella, Virginia Water, and getting into the walled garden with the pack at its heels and the huntsmen a long way behind. The local papers tell of there being in the garden two long parallel forcing pits, about a yard apart, covered with glass lights. As the stag was driven about it leaped one range of lights and went crash into the other, smashing the glass and cutting itself fearfully. Getting out, it again repeated the exploit, with again shocking results. Could the poor mangled animal have spoken as freely as doubtless the gardener did, we might have well imagined what it would have said. Alas! that so shocking a sight should be tolerated in our country.—A SURREY GARDENER.

— GARDENERS AND SPECIALISTS—DEAR CABBAGES.—At the annual dinner of the Lincoln Gardeners' Association held last week, Dr. G. M. Lowe presided over a company of about seventy members. The Rev. C. C. Ellison, in proposing success to the Association, seems to have pleased the gardeners by allusions to what he described as "unfair" claims on them, and recounting his experience with Cabbages. He is reported to have said:—"All the delicious fruits and vegetables we possessed, and the other knick-knacks a cook required were provided by the gardeners; it was they who provided the flowers that decked the bridal procession; it was they who provided the flowers which were one's last tribute to the dead, and yet they were a most ill-used body; and for this reason—people were too exacting. Take the members of his own family for example. One girl would come back from a visit somewhere and say, 'I have seen such splendid Tulips; why can't we have Tulips?' Well, she would go and worry the gardener, and it would end in £4 having to be spent in Tulips. Then another would come home and say, 'I have seen such lovely Petunias, why can't we have Petunias?' and so the thing went on. They went to specialists in one flower, and then came home and wanted to find in their garden 50,000 specialists rolled into one. That was exceedingly unfair, and he thought himself if a gardener made the best use of the facilities he had it did him the greatest credit. It was always a great delight to him to find a man with limited means produce anything exceptionally perfect, and one day when looking round a small garden in Derbyshire he highly praised the owner on his success in growing tremendous Red Cabbages, and told him he had not anything nearly so large even in his own garden. As a matter of fact he had not any at all. The man promised to send him one or two after a time, and he (Mr. Ellison) one day had actually to pay 3s. 6d. carriage for two Red Cabbages. And that was not all, for the cook pickled the monstrous things, and his meat bill went up 35 per cent., the family having to eat so much more meat to get the pickles put out of sight." There seems also to be a "Dahlia and Aster Society" in the ancient city, which has been celebrated by a largely attended dinner. The object of the Society is to "increase the interest in the cultivation of Dahlias, Asters, Stocks, and a few other flowers such as adorn the gardens of the working classes." The annual shows are said to have been very successful over a period of five years.

— CORRECTION.—"W. G." writes:—"Kindly make the following correction in your next issue—viz., that in my remarks on John Cox and Napoleon's Willow on page 105 I inadvertently used the name John instead of David, thus implying there may have been two famous Birmingham painters of the name Cox."

— SEEDLING COLEUS.—Large as are the number of varieties of named Coleus at present in cultivation, many of them are superseded by the beautiful forms appearing from the purchase of a packet of seed. I am now referring more especially to the large leaved varieties, which are splendid in habit and of great importance for decoration. When in Ireland last summer I almost marvelled at the glowing shades of leaf colouring and their charming formation. On making inquiries, I was told that the plants were from seed, the strain being The Sunset, which I believe is of American origin. To anyone purchasing a packet of this particular strain and sowing at the present time in sandy soil, in warmth, I can assure them that they will be amply repaid for their trouble.—R. P. R.

— FORCING NARCISSI.—I notice from the report of the meeting of the R.H.S. at the Drill Hall on January 31st, not the least interesting exhibit was that of forced Daffodils and Poet's Narcissus. The display would doubtless impress still further on those who saw it the usefulness of this class of flowers for forcing purposes. We have got so used to depending on Holland for our supply of spring bulbs that the possibilities of providing for ourselves with English grown bulbs has perhaps been overlooked. It is questionable, however, whether this will be so in the future. The taste for Daffodils and other spring-blooming bulbs has taken a firm hold on the flower-loving public, and it is surprising that the adaptability of our soil for their growth has not been found out before. It has been proved that home-grown Narcissi lend themselves readily for forcing, and it is not unlikely that their chaste and elegant forms will supplant the stiff and formal Dutch Hyacinth.—H. G.

— BULLFINCH SLAUGHTER.—Thirty or forty years ago, bullfinches and goldfinches were not at all uncommon amongst the orchards of North Kent; now, in this district, they seem to be extinct. The goldfinches have been ruthlessly captured by London dealers, some also of the bullfinches, but that species has suffered more from the guns of gardeners and fruit growers, having long had a worse character than it deserves. All its friends must admit that a bullfinch will make free with a ripe Cherry or Plum, and it will attack buds, yet, on the other hand, it is certainly a feeder upon insects. No one who has seen the eagerness with which one will devour the aphides held to it on the tip of a moist finger can doubt that these pests form part of its natural food. Very likely, too, its visits to buds are prompted by an appetite for the caterpillars and grubs lodged in many of them. As with others of the finches, the diet is mixed, but the bird is so docile, affectionate, and sagacious in confinement that it may well appeal to our kindly feelings towards the race, even if it does some harm.—J. C., *Gravesend*.

— ROCK PLANTS AT ABINGER HALL.—At Lord Farrer's seat near Dorking an extensive rockwork, one of the home-made description, and therefore, as a rule, far more suitable for all sorts of hardy plants than very elaborate ones are, had when I looked over it on the 9th some early and very interesting things in bloom. Crocuses Imperati and Sieberi, both of blue shades, were charmingly flowering; so also was Cyclamen coum. The pretty Ionopsidium acaule was flowering also, and had been in bloom nearly all the winter. Of Snowdrops, Galanthus Elwesii was blooming here and all about the grounds, so also was the yellow Aconite, which was occasionally seen in large quantities. Strange was it to see Sarracenia purpurea doing well outdoors, and whilst bearing numerous good pitchers, also exhibited rich colouration. Iris stylosa with stylosa alba, and I. histrio were flowering charmingly, the former having been so for some few weeks previously. It is a most valuable plant to produce very early flowers. A pretty Primrose is named Primula olympica, the flowers being of a pale purple colour. Very early in bloom, too, were Saxifragas Boydi, white, very small cushion-like plants; also Frederica angustifolia, yellow. Very strange, and evidently unusual, was it to see Primula rosea growing in great quantities round the margin of a pond, the roots quite in the water, and apparently liking it. P. japonica also was doing wonderfully well under the same cold water treatment. The rockwork includes a remarkable variety of alpines. Numerous Dianthus, Aubrietias, Tiarella cordifolia, Alpine Phloxes, Lithospermums, white Primroses, Hellebores, Gypsophila prostrata, Omphalodes verna, and many others. Mr. Payne, who made and planted the rockery, has every reason to be proud of his construction now that it is so well furnished.—A. KINGSTON.

PEACHES AND NECTARINES.

(Concluded from page 101.)

WE now come to the fruit thinning, which should be done with discretion. If the trees are healthy there is not much fear of the fruit dropping during the stoning process, especially if they are not allowed to suffer for want of water. Therefore I should not advise many more fruit being left to go through that period than are to remain to ripen. If the fruits are about 9 inches asunder each way the crop will be a good one, and will be quite sufficient for an ordinary tree to carry.

As soon as the fruits commence to swell after stoning, frequent applications of liquid manure will be beneficial. If liquid cannot be had, a little chemical, such as a handful of guano spread round the trees and well watered in about once or twice a week, will be of assistance. A mulching of half-decayed manure will help to retain the moisture in the soil in hot weather. Remove all foliage covering the fruit, so as to encourage the development of colour, and when signs of ripening are apparent syringing must cease, the trees being kept as dry as possible to prevent cracking of the skin.

Gathering ripe Peaches requires the utmost care, the slightest bruise will show, and the value will be lessened proportionately. Nectarines are not quite so tender, but they, too, must be judiciously handled. Some growers prefer to gather the fruit before it is quite ripe and thus obviate damage, but I do not agree with that except for packing purposes, as the fruit has not the flavour it would have if left on the tree to finish. The best plan, I think, is to have a shallow box lined with wood wool. When picking get the fingers well under the fruit and gently raise it; if it is ripe it will fall into the palm of the hand and can be placed in the box, not allowing the fruit to touch one another. In a cool house or room they will keep for several days.

I will now say a little regarding enemies and diseases, taking the black fly first, which will appear as soon as the buds begin to burst. Out of doors this is difficult to combat, especially when it appears so early. I have found that a sheet over the tree, and fumigating as well as possible, if not a sure cure, will keep the little intruders at bay until liquid insecticides can be used. Green fly is the next, but it does not appear until the shoots commence to push. It is frequently encouraged by a check through cold winds and draughts. The pest can be eradicated by carefully syringing with some approved insecticide. Thrips and red spider are easily kept away by frequent syringings of clean water during hot weather, while brown scale can be dealt with when the trees are dormant by painting with a solution of soft soap and paraffin thickened with clay or cow manure. Weevils are very destructive, and must be searched for at night and picked off.

Mention having been made of the insects, I will turn to the diseases, and mildew—to which some sorts are more addicted than others—must have primary attention. Cold damp weather is the most general cause of this disease, or a cold border, but in either case flowers of sulphur dusted over the affected parts is a good and simple remedy. Syringe the trees thoroughly to wash the sulphur from the fruit. Gumming is often caused through too rich a soil, which is conducive to sappy wood that does not ripen sufficiently. Fruit cracking at the stone, as in the previous case, is the result of rich soil, or over-supplies of food, or damp weather at the period of the second swelling.

Having dealt with outdoor culture, let us turn to the forcing house. If we require Peaches ripe about the first week in May, the house must be closed by Christmas. The trees should be pruned, painted if necessary, and tied back in their places. Rake off the old surface soil, or if this is too full of roots, lightly loosen with a fork, and apply a coating of loam, mixing with it a little lime rubbish, wood ashes, and chemical manure. This having been done, the borders should have a thorough watering. If the house is closed a week or so before Christmas, heating can commence with the new year, and must be done sparingly at first, the temperature not being allowed to rise higher than 50° to 55° by day, and 45° to 48° by night.

Frequent syringings of tepid water should be given to aid the buds in swelling, and little if any air will be required, unless the sun is very warm, until the flowers are open, when the syringing must stop, and the house be kept as dry as possible. Abundance of air should be admitted when the weather permits, but avoid draughts. Gently shake the trees about midday until the fruit is set. When this period is reached, the temperature can be slightly raised, renewing the sprinkling to remove the decayed flowers. The disbudding and tying must be done precisely the same as with trees out of doors, while syringing ought to be attended to twice daily, damping round the pipes and dry corners to prevent red spider and thrips.

Watering should not be neglected, trying as nearly as possible to use water of the same temperature as the house. Discretion must be exercised in thinning the fruit, retaining those on the top of the trellis where they will get most sun and light for colouring. As soon as the stoning process is over a little harder forcing can be commenced,

feeding the trees occasionally. If good stable manure is available shake out the droppings and put a layer of straw on the border, as it saves the fruit from bruising if it should drop, and keeps the borders moist during hot weather. As soon as the fruit shows signs of ripening syringing must cease, and all leaves covering fruit should be removed. Admit air night and day, as Peaches develop a better flavour when steadily ripened. When the trees are cleared of fruit cut out all old bearing wood and shorten long slender shoots. Apply plenty of water at the roots, and well wash down with a hose, if available, three or four times a week. If root-pruning is thought necessary it ought to be done as soon as the wood is ripe and the leaves fall.—S. H. SNELL, *Fruit Farm, Torquay.*

SOIL ANALYSES.

ON my introduction of the subject, under "The Soil," page 455, previous volume, I had hoped, on feeling myself supported by the Editor in his footnote, that correspondents would have enriched the field, instead of that a side issue seems to have been introduced.

In respect to "English Gardener," instead of chopping words I prefer to limit myself to referring him to my earlier suggestion, on page 48, that the utter want of homogeneity of the soil he works, as judged from his experience from ten analyses, all varying materially, would render the application of a gardener's instinct requisite to direct the management, in place of analysis primarily.

If I now abandon matters as unprofitable, and of no advantage to horticulture, I thus should like to resume that common sense tells me about the existence of various soils from the remote recesses of the creation as well as from disintegration and denudation. Hence analysis of the soil becomes an interesting question.

In this we have no need to go the length of the materials used for pot experiments. There are manifestly large stretches of alluvium, composed of endless variety of materials from disintegration of manifold rocks filling river areas from encircling watersheds, as is done to this day in the annual Nile deposits in Egypt, and there analysis of the soil is destined to figure usefully, as it may in numberless other areas.

The "Times" of 15th September last said, in reference to agricultural research, that the feature deserving of special mention was the arrangement made by the Dorset County Council for an exhaustive series of analyses of typical soils by the Agricultural Department of the Reading College. I presume such varying analyses would be discussed as part of the instruction, and the most fertile among these be extolled, which in any inquisitive mind would result in the query: "I wonder what my soil would prove to be like were I to analyse?"

Mr. Cousins himself thinks necessary to say in his primer that, if his little book has a special gospel to preach it is that of lime; and when asking why are these or other crops deficient, the answer is, because in nine cases out of ten lime is deficient, which, he adds further on, is the chief basis of fertility of the soil. It is thus, according to this authority, a fact that not more than one in ten gardeners, when deficiency of crops occurs, have thought of lime in time. I presume because analysis was considered unnecessary.

I find some authorities holding that analysis of the soil is analogous to the utility of the compass to the sailor. Indirectly yes. But the sailor requires his chart and sextant to render his compass most useful, and it is rather these that are the equivalents of an intelligent system of analysis of the soil. In the result of this discussion I should like to find my place among a body of gleaners in all that the soil produces on that broad expanse of common sense, broader than the British Empire.

It may be interesting generally on this topic to hear what Professor Meldola wrote a couple of years ago as to the character of contributions by writers who are not experts. He said that they were often capable of taking a wider and more philosophic grasp of a problem than a pure specialist, and ideas of lasting value had sometimes emanated from such sources. He adds that his object is to claim more consideration for such writers as a class on the part of practical workers, and thinks that the philosophical faculty is quite as powerful an agent in the advance of science as the gift of acquiring new knowledge from observation and experiment, and that it is not often that the faculties are combined in one individual.

My aim in contributing is of a constructive order to the edifice, and not destructive, except to rule-of-thumb methods.—H. H. R., *Forest Hill.*

[We have abridged this communication as we have all others on the subject; and as we think "An English Gardener" will find as much in the present rejoinder with which he may be disposed to agree as he would be likely to find if the controversy extended over six months, and as it has already reached the "Nile," it may well cease.]

PROGRESS AND PROSPERITY.

THOUGH the actual end of this nineteenth century is not yet with us, we have not now long to wait for the time when the papers of the universe will teem with articles on the world's progress or retrogression during the past one hundred years. That horticulture will have a prominent position in any records of this nature goes without saying, and the writer's task will be no easy one who commences an essay on "The Century's Progress in Horticulture." But while immeasurable strides have been made in gardening during that period, the results attained to in more limited spaces of time can be termed nothing short of marvellous, and the pen of a fluent writer in the hands of a student would find no mean task in taking the century in decades, and treating of the rise and fall of particular plants. Someone will probably undertake this work, and if it be done properly it will form as interesting a series of articles as has ever appeared in the columns of the gardening press. It cannot, however, yet be said what this dying century may bring us, but it will be something more than miraculous if the paragraph respecting Orchids that went the rounds of the daily papers a week or two ago prove true. Let us trust it will not, or all our Orchid works will need to be rewritten.

It is not proposed now to attempt such a task as that just outlined, but to glance at the advance that has been made in Primulas and Cyclamens during the years 1879 to 1898 inclusive. To further reduce the scope of the undertaking only one firm's work will be noticed, that of the great Reading house of Sutton and Sons. From the fact that 1879 is given as the primary date it must not be inferred that the cross fertilisation of Primulas and Cyclamens did not commence at Reading previously—indeed, for a very extended period prior to that the work was being pressed forward with judgment and discretion. This particular year is specified simply because it marked an epoch in the progress of Primulas, for it was then that Ruby King was given forth in all its striking beauty. It was the attainment of prosperity after assiduous labour, and from then till the present progress and prosperity have gone hand in hand, for no year passed that did not bring some speciality that was an advance on its predecessors in at least one respect.

That this same Ruby King was a Primula of Primulas is more than proved by its popularity to-day, for since its inception scores of varieties have come and gone. They have remained for perhaps half a decade or less, and then have sunk to oblivion. True, few of the varieties from Reading have received this fate, as the care in testing every one before it is placed in commerce is so great that when a variety does come it is to stay. As typical to a certain degree of the improvements that have been made look for a moment at the illustrations (figs. 26 and 27). The former depicts the Star Primula of to-day, the individual flowers of which will convey an idea of what material was in bygone days available. Then observe the second photographic reproduction, which portrays Sutton's Giant White Primula, and a rough estimate can be drawn by anyone. In the latter there is every desirable attribute that goes towards the making of a perfect Primula. It must, of course, be borne in mind that the modern Star is far more floriferous than *P. sinensis*, and in forming judgment the flower alone is examined.

On a parallel with Ruby King, in age as well as in excellence, is Pearl, which, needless to say, is white in colour. Looking some weeks back at a number of plants *en masse* in one of the Reading houses the conviction that it remains one of the finest was forced upon us. The

habit of the plant is splendid, both in the leafage and its mode of carrying the flowers. But too much space must not be given to the old-timers or the amount available will be exhausted, with consequent neglect to those which, if they have not reached their majority in years, have passed it in other more important respects. To those whose fancy trends in the direction of large, symmetrical, substantial flowers, with correspondingly handsome foliage, must be commended the giant section. As a class these plants were not at their best when this visit was paid, but sufficient examples were in evidence to warrant the highest eulogium on the white, pink, and crimson varieties. The plant (fig. 27) admirably represents the first named. For late flowering these Primulas are invaluable, and make a most striking display over a very considerable period, this being longer or shorter in accordance with the system of culture adopted.

Belonging to the same section of *Primula sinensis* as Ruby King and Pearl there are a larger number of varieties from which to make a

selection, and all are of different habit from the giants just mentioned. Here we have compactness of growth in the plants, with floriferousness, refinement, and a more diversified range of colouration. Broadly speaking the flowers are from medium to large in size, very stout in the petals, some plain and others fimbriated, but all closely approaching to an ideal form. As the most striking of the whole must be named Crimson King, which is quite a new one that is placed in commerce for the first time this year. It is remarkable as well for its persistent blooming tendency as for the intensity of the velvety crimson colour, the effect of the flower being decidedly accentuated by the black band that encircles the yellow centre. The richness of the bold trusses standing well above the clear green leafage entitles Crimson King to be styled a perfect Primula. What is perfection at the present may not hold that rank next year, but it is more than probable that the one now referred to will hold sway over several years. No one, however, knows what the Reading firm will produce, so it is not wise to make predictions.

Comparable with Crimson King, and notwithstanding its super-excellence, fit associates for it are Rosy Queen and Purity, whose specific names tell their particular hues. The softness of the tone of the former, its freedom of flowering, and its fine habit justify every word that has been from time to time said about it. Of Purity no more need be added than that it is wholly worthy of its name. As one trio has now been formed we would fain suggest another

that will be little less striking than its predecessor, though it will not include an 1899 variety. It shall comprise Sutton's Reading Blue, Reading Pink, and Gypsy Queen. Of the first named it can justly be said it is a blue, and that the large yet refined flowers over the charming green-leaved plant place it amongst the most desirable Primulas in cultivation. The shade of colour in Reading Pink is peculiarly fascinating, and it is exceptionally profuse in the production of its flowers. What reader of the *Journal of Horticulture* desires a description of Gypsy Queen? None, for it is assuredly one of the most widely known and universally appreciated Primulas in cultivation. Then there are Reading Scarlet, which, seen in a mass, seems to glow with fiery brilliancy, and Snowdrift, which for earliness has no compeer. Others find a home at Reading, and do their share towards the magnificent display, but they must wait for another year ere receiving individual mention.

Double Primulas have long enjoyed a favour that is not accorded to all plants, but their beauty is such as commends itself to everyone. Go where one may, in large places or in small, double varieties of Primulas

FIG. 26.—PRIMULA SUTTON'S STAR.

are seen in varying stages of excellence, and they meet with general admiration. That they are valuable, nay indispensable, in the winter is recognised, and it is only natural their widespread popularity should ever increase. Needless to say Messrs. Sutton & Sons have exerted themselves to enhance the beauty of this as well as the single section, and with unqualified success. The flowers of their strains have size without coarseness, richness of colour with refinement, and a constitutional strength that practically insures success in growing them. The colours represented are scarlet, pink, blue, crimson, white, and carnation flaked. Each has its admirers, and there are many persons, who like the writer, swear allegiance to the whole of them. One of the varieties of the future is a double prototype of Crimson King, if it maintain the promise now manifested which, must prove of the greatest excellence. But time alone can settle the point, and it is one of the many Primulas at Reading towards which many eyes are turned in pleasurable anticipation.

To go to Reading in January to formulate notes of the Primulas and neglect the Cyclamens *in toto* would be an unpardonable omission, for they are no whit less interesting, beautiful or excellent. The thousands of plants form an object lesson in Cyclamen culture that might be advantageously studied by many growers, though it does not follow that they would afterwards be qualified to attain to such results. The plants are almost wholly quite young, and are flowering in 5-inch pots. From the corms of all of them rise stout footstalks, carrying thick, handsomely marbled leaves, and from 150 to 200 flowers, a few plants having a diameter of upwards of 20 in. From these figures the practical reader can imagine what a picture was displayed for the visitor's admiring gaze. Not a single stake for the support of flowers or leaves was discernible, simply because artificial support is not requisite where the inherent strength of the plant was sufficient. Obviously excellence of culture has great effect on the results achieved, and everyone must admit that as a cultivator as well as a hybridist Mr. James Martin is a man among men.

With these as with Primulas there are two clearly defined sections—namely, *C. persicum* and *C. p. grandiflorum*. Both classes are worthy of a place in every establishment, but individual taste must decide which shall be the more extensively grown. The large leaves and bold upstanding flowers of the latter must command admiration from all. There is not in the leafage that beautiful marbling that is characteristic of the *persicum* section, and for which alone the plant might advantageously be grown. Then the smaller flowers are more freely produced, and are perhaps of a more refined type. Be this as it may, the forms of *grandiflorum* known respectively as White, Cherry Red, Crimson, and Crimson and White are magnificent, and will only be equalled in the estimation of some observers by Pink, Rose, and Purple. It resolves itself into a matter of individual tastes, and very fortunately everyone does not think alike.

In the *persicum* section there are two which stand far above the others from our point of view, and they are Salmon Rose and Vulcan. Of the former we should honestly say that it is the best Cyclamen in cultivation, for its qualities are such that there remains nothing to be

desired. Vulcan, too, with its intense dark crimson flowers is a plant that ought to be found in bloom in every garden in January, and as much before and after that time as the skill of the cultivator will allow. White Butterfly is exquisitely beautiful, as are scores of others to which varietal names have not been attached. But late though it may now be, let all who can go at once to Reading to see and to admire, and to mentally, at any rate, corroborate all that has been said in the preceding notes.—H. W.

NOTES ON PEAS.

BOXES *versus* POTS FOR EARLY SOWING.

PERHAPS another method of raising Peas under glass adopted by the writer may prove interesting, in addition to those given on page 89. It

consists of the use of a primitive type of flower pot, used largely in some establishments in the north and mid-land counties, and known as "collars." These are made very cheaply by brick and tile manufacturers, and are formed by cutting an ordinary 3-inch clay drain pipe into three portions prior to baking.

The collar is placed perpendicularly on a firm bench, and a square of turf rammed tightly into it to make a bottom. A round piece of wood a little smaller than the interior of the pipe is used for this purpose, and after placing a thin layer of soil over the turf, a few peas are sown, and these, again, are covered with soil. The pipes are then placed close together on a moist foundation in a cold house or frame until the peas germinate and the hardening process commences. The roots by planting time have not only taken possession of the soil, but have also penetrated the turf bottom, and in order to remove the plants without undue injury a round piece of wood is again brought into use large enough in circumference for the pipe to slip over it.

Then by taking the latter in both hands, and fixing the ejector in a perpendicular position, the plants may be pushed out of the collars with a little pressure, and without damage. The Peas are then planted closely together in the rows,

and after results have proved this to be an economical and convenient way of treating the earliest sowings of these vegetables made under glass. These substitutes for flower pots are also used largely for bedding plants in the spring, raising Sweet Peas and other annuals, as well as early sown Greens and Onions.—H.

FOR years I have adopted the plan of raising Peas under glass to enable us to gather pods earlier than was possible when sowing in the open. I have long since come to the conclusion that 3-inch pots are the best receptacles for sowing. To obtain an early crop of such varieties as Duke of Albany or Duchess for a show in July it is almost impossible to obtain them by ordinary sowing in the open.

Much valuable time is then gained by sowing five seeds in a 3-inch pot in a cool vinery or Peach house, and better results will accrue if the plants, without disturbing them separately, are shifted into 5½-inch pots in tolerably rich soil. Place a few twiggy stakes around the side of the pot,

FIG. 27.—PRIMULA SUTTON'S GIANT WHITE.

and to these the tendrils will cling. Numerous roots are made while the growth is vigorous and healthy. When planting time comes around the plants are fully 1 foot high and especially healthy, and start at once into free growth. The sowing of a quantity of Peas in small pots may entail more labour; but I am sure the efficacy of the system well warrants the extra trouble involved.—E. M.

PEAS AND VERMIN.

AS attention is now being turned in the direction of Pea sowing, precautionary measures have to be taken in many places against mice and other vermin which devour the seeds whilst they are in the ground. A few years ago it was my lot to have to grow Peas in a kitchen garden partially surrounded by a wood. Out of this natural shelter the sharp-pointed field mice came in great numbers, and were responsible for the spoiling of more than one promising row of Peas by extracting the germinating seeds from the ground and partially devouring them. Baited traps were set, and many of the pests caught, but still the mischief continued until a simple preventive was adopted, and proved successful in stopping the ravages of the mice.

The *modus operandi* consisted of placing dry powdered red lead in a shallow box. The peas just prior to sowing were moistened with water and rolled about in the powder. The moistening causes the red lead to adhere to the peas, and in that condition they were scattered in the drills. I never knew the dressing to have any effect on the germination of the seeds, though I have heard the matter questioned as to this. The method of treatment is simple, and proved quite successful in checkmating the mischievous creatures which caused such annoyance before its adoption.—G.

CONSUMPTION OF POTATOES IN THE UNITED KINGDOM.

THE Potatoes consumed in this country are for the most part of home production, imported varieties constituting only a very small proportion of our annual supply. The area devoted to the cultivation of this vegetable in the United Kingdom is, according to the latest agricultural returns, about 1,200,000 acres, whereas thirty years ago, when the returns were first collected, the extent of land similarly cultivated was estimated at 1,600,000 acres.

The loss of 400,000 acres in the total area is mainly due to a large contraction in the Irish acreage. In England and Wales there has been comparatively little change, the slight decrease in the principality being more than counterbalanced by an extension in England. Relatively to population, the British area now represents an acre for every sixty-eight persons of the population, compared with an acre for every fifty persons thirty years ago; while in Ireland, where a partial abandonment of the crop has been to a large extent consequent upon a reduction of the population, the personal ratio is now roughly equivalent to an acre for every seven persons, as against an acre for every five at the earlier period.

Estimates of the quantity of Potatoes produced in the United Kingdom, exclusive of the Channel Islands and the Isle of Man, have been published annually since 1884; but for Ireland alone estimates of production are available for the past thirty years. The average estimated yield per acre during the past five years for the entire country has been 4.62 tons. The Potato fields of Great Britain alone yielded in that period 6.05 tons per acre; but in Ireland the average crop per acre turned the scale at only 3½ tons.

Our average requirements of Potatoes for all purposes would appear from the above figures to amount to about 5,500,000 tons yearly. Of this quantity all but 3 per cent. is furnished by the home production.

The Channel Islands and France are the principal purveyors of the small imported supply. From the former we receive annually nearly 60,000 tons, and the consignments from France amount to between 40,000 and 60,000 tons in the year. The imports from the Channel Islands consist almost entirely of early varieties which reach our markets before the British crop is ready for lifting, and consequently command a higher price. Their average declared value in recent years has been from 9s. to 9s. 6d. per cwt., whereas the French cargoes have usually been valued at 5s. to 6s. 4d. per cwt. Germany, Holland, and Belgium are the more important of the other countries distinguished in the trade returns as exporters of Potatoes to this country.

The total exportation of Potatoes from the United Kingdom to all countries last year only slightly exceeded 24,000 tons.—("Journal of the Board of Agriculture.")

— SWEET PEAS.—Where a quantity of these charming flowers is required through the summer for decorative purposes, it is well to insure an early supply of bloom by commencing with plants raised under glass. Some growers advocate sowing out of doors early in February, but my experience is that the seeds invariably lie in the soil some time before germinating, and the tiny seedlings are in danger of slugs and other enemies as soon as they show through the surface. I therefore prefer to fill a number of 4-inch pots about half full of old potting soil, and on this scatter about half a dozen seeds, covering them with soil nearly up to the rim of the pots. The latter are then placed close together in a frame or near the glass in a cool house. They are grown cool and retain a sturdy habit till they can be safely planted outdoors. Treated in this way no enemies affect them, and earlier flowers are obtained than by sowing outdoors.—G.

ROYAL HORTICULTURAL SOCIETY.

ANNUAL GENERAL MEETING OF FELLOWS.

THE meeting of Fellows at the Society's offices on Tuesday afternoon, under the presidency of Sir Trevor Lawrence, Bart., was a moderately large one. Amongst those supporting the Chairman were the Rev. G. H. Engleheart, Sir J. T. D. Llewelyn, Bart., and Sir W. T. Dyer, with Messrs. T. B. Haywood, H. J. Veitch, H. J. Elwes, C. E. Shea, and P. Crowley, while in the body of the room were amongst others Messrs. G. Paul, G. Bunyard, G. Wythes, G. Gordon, H. J. Pearson, C. E. Pearson, J. Willard, R. Dean, A. Sutton, H. Selfe Leonard, H. Turner, W. P. Wright, H. H. Raschen, A. Dean, and J. Douglas, the two latter being appointed scrutineers of the ballot for the election of members of the Council.

REPORT OF THE COUNCIL FOR THE YEAR 1898-99.

THE year 1898-99 has been one of increased prosperity for the Society.

The Council have felt justified in spending a considerable amount on the Lindley Library, namely £170, to assist the Trustees in completing and publishing a catalogue of the library, and also in purchasing various books which the catalogue showed to be wanting.

The catalogue was published in December at a price of 2s. 6d., in the hope that many Fellows would purchase it, not only to inform themselves what books the library contains, but also because it forms in itself a sort of reference list to the bibliography of gardening. Some Fellows might also take note of books still wanting to the library, with a view to presenting them.

During the past year valuable books have been presented by the Director of the Royal Gardens at Kew, Dr. Maxwell Masters, F.R.S., T. J. Bennett-Poë, Esq., Miss Ormerod, Mrs. Holborn, Signor Alnio, and many others, to all of whom the best thanks of the Society are due. A full list will be published on April 1st in the Society's Journal, vol. xxii., part 4. Acting in conjunction with the Trustees, the Council have purchased for the library:—"The Silva of North America," Prof. Sargent; "The Flora of Northern America," Britton and Brown; "Nature," from its commencement, fifty-six vols.; "Flora of Tropical Africa," "Flora Germanica," Reichenbach, twenty-two vols.; "Flora Pyrenaica," Bubani; "Atlas des Plantes," Bois; "The Water Garden," Tricker; "Flora of Berkshire," Druce; "Chemistry of the Garden," Cousins; "Garden Making," Prof. Bailey; "British Orchids," Webster; and others.

Under the head of ordinary expenditure at Chiswick, £1850 has been spent on the general work and maintenance of the gardens. Amongst other work, house No. 9 and the potting shed attached thereto have been painted and thoroughly repaired, houses Nos. 3, 14, 16, and 21 have all been repaired and painted, as have also many of the frames. All this work has been done by the Society's own staff of men. The receipts by sale of surplus produce amount to £357, making the net ordinary cost of the gardens £1493.

At Westminster twenty-two Fruit and Floral meetings have been held in the Drill Hall, James Street, Victoria Street, and seven Committee meetings have been held at Chiswick, besides the larger shows in the Temple Gardens on May 25th, 26th, and 27th, and at the Crystal Palace on September 29th, 30th, and October 1st. Lectures have been delivered at nineteen of the meetings. The number of awards granted by the Council, on the recommendation of the various Committees, has been as follows:—

AWARD.	At Provincial Shows.	Affiliated Societies.	On Recommendation of				Total.
			Fruit Committee.	Floral Committee.	Orchid Committee.	Narcissus Committee.	
Gold Medal ...	1	—	5	5	3	—	14
Silver-gilt Flora ...	3	—	—	32	7	—	42
Silver-gilt Knightian ...	—	—	16	—	—	—	16
Silver-gilt Banksian ...	1	—	5	34	—	—	40
Silver Flora ...	4	14	—	70	12	5	105
Silver Knightian ...	—	—	22	—	—	—	22
Silver Banksian ...	6	26	28	74	28	3	165
Bronze Flora ...	1	8	—	6	—	—	15
Bronze Knightian ...	—	—	—	—	—	—	—
Bronze Banksian ...	—	22	5	12	5	1	45
First-class Certificate ...	1	—	11	26	31	4	73
Award of Merit ...	—	—	49	167	68	8	292
Botanical Certificate ...	—	—	—	3	16	—	19
Cultural Commendation ...	—	—	32	3	23	—	58
Total ...	17	70	173	432	193	21	906

In addition to the above:—One silver-gilt Flora medal has been awarded to Miss O. Harrison for having passed first in the Society's examination and four Hogg Memorial medals have been awarded; eighty-five bronze Banksian medals have also been granted to Cottagers' Societies.

The Council are fully aware (as all Fellows visiting the Drill Hall shows must also be) how very meritorious the groups of flowers, fruits, vegetables, &c., are, and how thoroughly, as a rule, they deserve the medals recommended by the Committees. The Council entirely recognise

the difficulty of the work of the Committees in decreasing the number of medals they recommend. At the same time they feel it their duty to urge upon all the Committees, and upon the individual members thereof, the necessity of gradually but continually raising the standard of excellence which they set before themselves in recommending awards.

Another point which the Council desire to suggest to the Committees, is whether groups exhibited by the horticultural trade, and groups exhibited from amateurs' gardens should be judged by exactly the same standard of excellence? Whether, except in cases of open competition for prizes, some slight favour should not be shown to encourage the latter?

During the past year the Society has been presented with the dies of a very fine medal, which has been struck, and subscribed for by numerous friends in memory of the late Dr. Robert Hogg. The Council have decided to restrict the use of this medal to the Fruit and Vegetable Committee, with which Committee Dr. Hogg was so intimately and specially connected from its very foundation in 1858.

On Tuesday, July 5th, the Council invited all the members of the several Committees to lunch with them at Chiswick, and to examine the Gardens. An account of the proceedings will be found in the Journal, vol. xxii., page 237.

An International Conference on hybridisation has been arranged for July 11th and 12th, 1899, to commence with a luncheon at Chiswick, to which all the Committees of the Society will be invited, and to close with a banquet in the Whitehall Rooms, Hotel Metropole, in honour of the distinguished foreign guests who are expected to attend the Conference. Full particulars concerning the Conference will be found in the Society's Book of Arrangements for the year 1899. Any Fellows desiring to be present at the banquet, and wishing for tickets for ladies or gentlemen, should communicate with the Secretary before July 1st. The price of the tickets will be 21s.

The Council desire to draw the attention of all Fellows of the Society to the more extended use which the Scientific Committee might be to them if they availed themselves more freely of their privileges in submitting instances of diseases of, or injurious to plants, caused by insects or otherwise. The Scientific Committee is composed of gentlemen qualified to give the best advice on all such subjects, either in respect to the prevention or cure of disease. The Committee is also glad to receive specimens of any subjects of horticultural or botanical interest.

That Fellows, whether near or at a distance, may derive as much benefit as possible from their connection with the Society, the Council last year appointed Dr. J. Augustus Voelcker, M.A., Consulting Chemist to the Society. They have renewed their arrangement with him, whereby all Fellows who are amateurs or *bonâ fide* gardeners may obtain at very small cost analyses of manures, soils, &c., or advice as to what description of chemical manure will be most suitable and profitable for application to any particular soil. The Council wish again to draw particular attention to the following points, viz:—

- (i.) That Fellows desiring an analysis must follow explicitly and exactly the directions laid down in the Book of Arrangements, 1899; and

- (ii.) That Fellows who are in any way commercially interested in any artificial manure trade or horticultural business cannot claim Dr. Voelcker's assistance as Fellows, but if they wish to consult him must do so in the ordinary way of business.

The Society's Great Show held in May (by the continued kindness of the Treasurer and Benchers) in the Inner Temple Gardens, was as successful as ever, and it is a matter of satisfaction to the Council to find that this meeting is now universally acknowledged to be the leading horticultural exhibition of this country. The best thanks of the Society are due to all who kindly brought their plants for exhibition, or otherwise contributed to the success of this Show.

The exhibition of British grown fruit, held by the Society at the Crystal Palace on September 29th, 30th, and October 1st, was, considering the very unfavourable season, most satisfactory. Full particulars will be found in vol. xxii., part 4 of the Journal, which will be issued in the course of a few weeks.

As an object lesson in British fruit cultivation this annual show stands unrivalled, and is of national importance. The Council invite Fellows and their friends to support it, for it cannot be too widely known that the continuance of the Show is absolutely dependent on at least £100 being raised by subscription each year towards the Prize Fund. The Show involves the Society in a very large expenditure without the possibility of any return. The Council have therefore established the rule that they will not continue it unless sufficient interest in it is taken by Fellows and their friends, to provide £100 towards the Prize Fund. Subscription for this purpose should be sent at once to the Secretary, 117, Victoria Street, Westminster, and if the list prove satisfactory the schedule will be issued in April, and the Show held on September 28th, 29th, and 30th, 1899. The list of subscribers for 1898 will be published in part 4 of vol. xxii., of the Society's Journal.

A deputation was sent by the Council, at the invitation of the local authorities, to attend the Great Summer Show of the Northumberland, Durham, and Newcastle-on-Tyne Botanical and Horticultural Society in July. Full particulars of this visit will be found in the Society's Journal, vol. xxii., p. cxiii. The Council desire to record the very great pleasure which this visit gave them, and their appreciation of the great courtesy and hospitality with which they were received.

An invitation has been received and accepted for sending a small deputation to visit a show of Daffodils and other early spring flowers and produce, to be held at Truro on the 21st and 22nd of March, 1899.

The Journal of the Society has been continued so as to enable Fellows at a distance to enter more fully into, and reap the benefits of the study and work of those actively engaged at head-quarters. Vol. xxi., part 3, and parts 1, 2, and 3 of vol. xxii., were issued during the year, and vol. xxii., part 4, will be ready on April 1st.

It is gratifying to record that the inquiry for the Society's Leaflet on Fruits for Small Gardens, Cottagers, and Farmers, continues. An entirely new and enlarged edition has been published, and may be obtained at the office at cost price.

The first edition of the **Book of Rules for Judging and Hints to Schedule Makers** which the Society drew up in 1896, has been exhausted. They have therefore been revised and reprinted, and an Appendix on Point-judging and Point-value has been issued. Price 1s. 6d.

An examination in the principles and practice of horticulture was held on April 5th, concurrently in different parts of the United Kingdom, a centre being established wherever a magistrate, clergyman, school-master, or other responsible person accustomed to examinations would consent to superintend one on the Society's behalf, and in accordance with the rules laid down for its conduct. No limit as to the age, position, or previous training of the candidates was imposed. One hundred and ninety candidates presented themselves for examination. The names and addresses of those who succeeded in satisfying the examiners, together with the number of marks assigned to each, will be found in the Society's Journal, vol. xxii., page 94.

It is proposed to hold a similar examination in 1899, on Tuesday, April 11th. Candidates wishing to sit for the examination should make application during February to the Secretary, R.H.S. Office, 117, Victoria Street, Westminster.

The thanks of the Society are due to all the members of the Standing Committees—viz., the Scientific, the Fruit and Vegetable, the Floral, the Orchid, and the Narcissus Committees, for the kind and patient attention which they have severally given to their departments.

The thanks of the Society are also due to all those who, either at home or abroad, have so kindly presented plants or seeds to the Gardens. A list of the donors has been prepared, and will be found in the Society's Journal, vol. xxi., part 4, 1899, which will be issued on April 1st.

The Council wish to express, in their own name and in that of the Fellows of the Society, their great indebtedness to all who have so kindly contributed, either by the exhibition of plants, fruits, flowers, or vegetables, or by the reading of papers, to the success of the fortnightly meetings in the Drill Hall. They are glad to find by the increased and increasing number of visitors that the Society's fortnightly meetings are becoming better appreciated by the Fellows and public in general.

A desire having been expressed that the so-called fortnightly meetings should be actually fortnightly throughout the whole year, it will be found by referring to the Book of Arrangements, 1899, that the Council have acceded to this request as far as it was possible to do so, having regard to such obstacles to absolute regularity as the Temple and Crystal Palace Shows, and the occurrence of Bank Holidays.

The papers read at these meetings, which have been or will shortly be published in the Journal,* are as follows :—

March 22nd, "Soils," by Mr. J. J. Willis, F.R.H.S.
 April 12th, "Insect Blights and Blessings," by Mr. F. Enock.
 April 26th, "Sweet Scented Leaves," by Mr. F. W. Burbidge, M.A., V.M.H.
 June 14th, "Hybrid Orchids," by Mr. J. O'Brien, V.M.H.
 July 12th, "Garden Peas," by Mr. N. N. Sherwood, V.M.H.
 July 26th, "Uses of the Bamboos," by Mr. A. B. Freeman Mitford, C.B.
 August 9th, "Water Lilies," by M. R. Latour Marliac.
 August 23rd, "Perpetual Strawberries," by M. Henry de Vilmorin.
 September 7th, "Disas," by Mr. T. W. Birkinshaw.
 September 20th, "Suburban Fruit Growing," by Mr. W. Roupell, F.R.H.S.
 October 25th, "Experimental Horticulture," by Mr. G. Gordon, V.M.H.
 November 22nd, "Garden Manures," by Mr. A. D. Hall, F.R.H.S.
 January 31st, "The Orchards of Nova Scotia," by Mr. Cecil Hooper, F.R.H.S.

Besides these lectures, the Rev. Professor Henslow, V.M.H., has most kindly given six floral demonstrations, short accounts of which have appeared in the Journal.

The following table will show the Society's progress in regard to numerical strength during the past year :—

[illegible]

* Back numbers of the Journal can be purchased by Fellows at reduced rates.

The Council have the sad duty of recording the death of forty-seven Fellows during the year, and among them they regret to find the names of Baron Ferdinand de Rothschild, M.P.; Lord Newton, Mr. Christopher Sykes, the Earl of Selton, the Earl of Lathom, Lady Cromer, Lady Repton, Sir Richard Quain, Sir Stuart Knill, Bart.; Sir James Bain, Hon. E. S. Parker Jervis, Professor Dr. Allman, Mr. Latimer Clarke, M. C. Bernardin, Dr. Johan Langé, Rev. D. A. Beaufort, Dr. T. Anson, Mr. H. M. Matheson, Mr. G. T. Clarke, Mr. Edmund Tonks, Mr. Charles Sharpe, Mr. T. B. Potter, and others.

A scheme for the affiliation of local horticultural societies was put forward in 1890, and 100 local societies have availed themselves of it. The Council express the hope that Fellows will promote the affiliation of local horticultural and cottage garden societies in their own immediate neighbourhood.

At the request of some of the Fellows, the Council have arranged to

send a reminder of every show (in the week preceding it) to any Fellow who will send to the R.H.S. Office, 117, Victoria Street, Westminster, twenty-four halfpenny post-cards, fully addressed to himself, or to whomsoever he wishes the reminder sent.

The Council recommend that (with the exception of the Secretary) the salaries of the principal officers of the Society—the Superintendent, the Cashier, and the Assistant-Superintendent—should continue as heretofore. The Secretary having now completed ten years of service to the Society, the Council recommend that an addition of £50 a year be made to his salary.

The programme for the ensuing year will be found in the Arrangements for the year 1899, lately issued to all Fellows.

Subjoined is the usual revenue and expenditure account, with the balance-sheet for the year ending December 31st, 1898.

ANNUAL REVENUE AND EXPENDITURE ACCOUNT FOR YEAR ENDING 31st DECEMBER, 1898.

HARRY TURNER
ALFRED H. PEARSON } Auditors. HARPER BROS., Chartered Accountants,
JAMES H. VEITCH } 10, Trinity Square, Tower Hill, E.C.

In moving the adoption of the report and the financial statement, which were taken as read, Sir Trevor referred to a few of the leading points in the report, which is given in full herewith. He spoke of the excellent status of the Society, of the splendid work done by the Secretary and other officers of the Society, and accorded a generous word of praise to the members of the various Committees. The fact of the Lindley Library having now been put in proper order was the subject of a few remarks, which included a well deserved tribute to Dr. M. T. Masters (who was

unhappily prevented from attending owing to indisposition), for his assistance in supervising the work done by Mr. Hutchinson. The crowding at the Temple Show was alluded to, as was the decision to reduce those immense displays that “were nothing short of gigantic advertisements.” One or two other items were brought prominently forward, but the state of affairs is so satisfactory that little had to be said. Sir W. T. Dyer seconded the adoption of the report, and was followed by Mr. H. J. Elwes, who spoke with force on one or two points, more particularly alluding to the Library and the awarding of medals.

SEASONABLE NOTES.

IN my notes, appearing in the issue dated February 2nd, I am made to say, "By no means prune until the end of *next* month." This would, strictly speaking, be March. I have no doubt the majority of readers will at once have realised that those notes were necessarily penned in January. Had it struck me at the time how far advanced we were in that month, I should have said February instead of "next month." When noting that little slip, it occurred to me that a few more seasonable notes might be given, and my main points in the present shall be upon pruning.

When to prune is a puzzle to many, because we have really good growers at variance with each other upon this point. For myself, I fully believe that more than half of our Roses are pruned from two to three weeks earlier than is beneficial, or that will bring us the best results. Too often we find our forward growth cut back by a late frost, and either irreparably injured, or so crippled as to give indifferent results. In reality we do not gain anything by premature pruning, because when Rose growth can move freely from the first, it develops quite as soon, and often before that which received a more or less severe check. By too early pruning we get growth from the best eyes or buds upon our plants, which we naturally cut back to.

This is why we prune—viz., to secure growth from the buds most likely to give us the best flowers. The whole operation and object of pruning lies in this fact. We know that all Roses break most freely from the terminal eyes upon each growth; and when these get active and forward, many are too anxious to prune. But if we are premature with the knife, we are only making our best and selected eyes the terminal ones upon the growths left, and often push them along too early. The second week in March for hardy varieties, and the first in April for those we know to be rather tender, are the dates I would choose.

Some growers prune very closely indeed when compared with others. In this respect we want to remember the purpose our Roses are to fill. If fewer blooms and higher quality are wanted, we need to prune considerably harder than if a number of medium quality are wished for, simply for decoration, whether in the garden or house. I am convinced that our so-called "Garden Roses," whether of climbing habit or not, are pruned much too closely. Especially is this the case with all climbers and others of extra vigour. Thin out the older wood in this case, and merely tip the longer rods of last year's growth. It does not matter whether they are growing upon walls, pillars, or are to be pegged down, there can be no question but what the most vigorous growth of the previous season is the most valuable during the coming summer, and I always endeavour to make as much room as possible for these rods.

The pruning of medium growers needs little comment. Here it is merely a question of shortening the growths more or less according to their strength; never losing sight of the main guide—viz., to cut back the weaker ones much closer than those of full vigour. Few growers thin out the old wood so closely as they might do to advantage. Nor do they cut away the weaker wood from the centre of their plants sufficiently to let plenty of light and air reach all sides of the most valuable growths. One can scarcely prune weak growers too closely. We make a practice of cutting these back to one or two sound eyes from the part where the last season's wood broke.

I would describe the methods of pruning more fully were it not that this has so frequently been done in the Journal, and by abler pens. What I wished to do was to point out a few common errors, and merely give a few hints as reminders to those who have not had a life long experience with our national flower. All stocks that were budded last year can be cut back close to the Rosebud at any time now. I do not pretend to say why these are not inclined to break into new growth so early as the eyes upon our Rose plants, but it is certain that such is the case, although they come on very rapidly after the first start.—PRACTICE.

HOW TO MAKE HORTICULTURAL EXHIBITIONS A SUCCESS.

THERE is no doubt that the horticultural exhibitions, held in almost every town and village of any size, do a great amount of good to those in the fray; but to the general public, whence the gate money is expected, there is year after year that sameness which must eventually cause a loss of interest, with a result that in many cases the shows have either to curtail the number of classes and reduce the prize money, or be discontinued. Good money prizes will undoubtedly bring exhibitors, but to entice the public, something besides first-class fruits, flowers, vegetables, and plants are required.

We are unquestionably a practical, and at the same time an excitable people, delighted with sensational performances and competitions of almost any kind. This being so, a thought struck me that we might inaugurate along with our flower shows practical competitions in the several branches of gardening, that would incite greater public interest and bring "grist to the mill," which is an indispensable factor in the carrying on of exhibitions. At our Chrysanthemum shows prizes might be offered for the dressing of blooms, the making of bouquets, potting, tying and staking plants, table decorations, and even fruit tree pruning, and many other things, which would be of greater interest to the general public than the things staged on the tables. At our summer shows no doubt much could be done in this way, which would result in pecuniary gain, in addition to being of great educational value to the on-lookers.

This being perhaps a most opportune time to discuss the question of "how to make horticultural exhibitions a success," the above remarks may not be out of place, but I trust will draw from others suggestions that can take a practical form. Personally I have no appreciation for shows where the exhibitors form the committee and outsiders are boycotted, as such cliquism benefits neither the public nor horticulture. —S. HEATON.

ABELIA RUPESTRIS.

THIS is a handsome plant for a cool greenhouse, having small oval shining green leaves resembling the Myrtle, and clusters of white tubular or inflated flowers, which are produced in succession throughout the

FIG. 28.—ABELIA RUPESTRIS.

greater portion of the year. Even in a small state this plant is very useful, but when planted out and having attained a good size it is especially beautiful. The accompanying engraving (fig. 28) shows the character of the flowers and foliage, the spray being cut from a plant grown in a light well ventilated structure in which only sufficient heat is employed to prevent the temperature falling below 40° in winter. In warm southern localities the plant also succeeds well trained to a wall. If grown in pots a mixture of turfy loam with one-third leaf soil and a little sand will be suitable; but it will thrive in any good garden soil when planted out if the position be not too damp.

THE YOUNG GARDENERS' DOMAIN.

MUSHROOM CULTURE.

MUSHROOMS if well grown will prove very profitable, and no doubt a few notes on their culture will be found useful to readers of the Domain. There are several different methods of procedure, but this article refers to those grown in cold houses.

The material to use for making the bed should consist of fresh horse manure with plenty of straw in evidence, merely removing the very longest, adding one load of tan to every five loads of manure, which will cause it to retain its heat for a longer period. Some prefer removing as much of the straw as possible, but I am of opinion that if this is done there is not sufficient heat to make the spawn run well. Turn the material alternate days to sweeten it and dissipate rank steam, and if in any way dry apply water, but on no account drench it. To tell if it be either too wet or dry, take a handful and press it together, and if in proper condition it will hold together without any water coming from it.

When the material has been properly sweetened the bed should be made forthwith in the form of a ridge, it being 2 feet 9 inches in breadth at the base and the same in height, allowing 4 inches across the top, with no limit as regards length, making firm with a fork as the work proceeds. Place a thermometer in the bed to obtain the correct temperature, and when the heat is falling and gets to 75° spawning should be done without delay, using pieces the size of hens' eggs a foot apart all over the bed and an inch deep. When this part has been performed place an inch of soil over the bed, beating well with the back of a spade to make the surface smooth. Cover the bed with clean straw, more or less according to the weather.

From three to four weeks after spawning it can be plainly seen if the spawn has done its work, as if so, the bed will look as it were covered with white threads, and if it appears to be dry, give a watering, using warm, soft water. In another fortnight Mushrooms will be ready to gather, and in doing so pull all the stems out of the bed with them; do not, on any account, cut them and leave the stumps on the bed, for they will decay and cause those growing round it to decay also. Watering should be attended to when necessary, using judgment in the matter. A little salt mixed with the water will often be found beneficial. When the weather is bright, it is good practice to remove part of the straw, giving the bed a light watering with a very fine rose water-can, and cover again as soon as it is done.

Mice and woodlice are often troublesome to the Mushroom grower. The former can easily be got rid of with ordinary traps, while for the latter I have found it a good plan to place flower pots filled with sweet horse droppings on their sides close to the bed, examining every few days, when woodlice in great numbers will be found lodged amongst it, and may be readily destroyed.—P. R.

THE MELON.

THE Melon still holds its own on the dessert table, and well ripened highly flavoured fruits are always in demand. The method of culture and the structures in which the plants have to be grown will, to a large extent, determine the time of sowing. For the earliest crops grown in heated pits seeds can be sown singly in 3-inch pots the first or second week in February, using a compost of two parts fibrous loam and one part of decayed manure. After sowing, the pots ought to be plunged in a temperature of 75° or 80°, giving no water until germination has taken place. When the young plants have attained a height of 4 or 5 inches, fill the pots with soil, previously warmed, place a neat stake to each plant to prevent damage, and stand them on a shelf where they can receive as much light as possible. If the plants are to be trained to a trellis in a house no stopping will be required.

About a fortnight or three weeks prior to the plants being ready for their fruiting quarters, the compost should be prepared and the house made ready. Wash the glass and woodwork and limewash the walls, if this has not already been done, and the bed or mounds may then be put in. The compost in which they are to grow may consist of four parts of heavy loam, one part each of spent hotbed manure and lime rubbish, a few wood ashes, and a little soot. From the time the plants are finally put out they will require careful and constant attention, airing, watering, tying, and pinching the lateral growths whenever necessary.

The night temperature must not be allowed to fall below 65°, with a rise during the day of 10° by fire, or 20° by sun heat. In admitting air, the cultivator must be guided by external conditions; if these be favourable a little air may be admitted by the top sashes, when the thermometer stands at 80°, increasing the amount as the internal and external heat rises; but care should be taken to avoid all cold draughts, or injury will be done to the tender young plants. The house must be closed early in the afternoon, so as to obtain the full benefit of the sun heat, and if after closing the temperature rise by sun heat to 90° or 100° no harm will be done, provided there is ample atmospheric moisture. If the plants require water at the roots it should be given at closing time, when the house is damped down; and if the day be fine the plants may be well syringed to keep down aphids and other insect pests, taking care that the water is of the same temperature as the house.

Attention must be given to training. Until the plants have reached the trellis all laterals should be pinched off, but from that time the laterals may be allowed to grow until the fruits appear, when they should be stopped one leaf beyond, also pinching the sublaterals at one leaf. The stopping of the laterals will cause the flowers to open rapidly, and these will require fertilising. Some growers defer fertilisation until a sufficient number of flowers are open to form a crop, and then commence

the operation, with a view to giving the fruits an even start, and so being able to ripen them at one time. For the market grower this may be advantageous, but to the private gardener no advantage can accrue.

When the fruits are about three parts grown, they can be supported by strips of raffia, nets, or other material to prevent them from being broken off. As the fruits attain maturity and commence ripening, they will require an abundance of air, a little with advantage being left on all night; while less moisture both at the roots and in the air will be needed, though the roots should not be allowed to become too dry. If the fruits are to be kept any length of time or to be packed and sent away, they should be cut a day or two before they are fully ripe, as by so doing they will keep longer, travel better, and their flavour will be improved. There are many varieties, and each cultivator has his own particular favourites, but the following will be found very good—Hero of Lockinge, Royal Favourite, Eastnor Castle, Blenheim Orange, Invincible, and Sutton's Scarlet.—S. P.

HARDY FRUIT GARDEN.

Planting Fruit Trees.—During open dry weather in the course of the present month fruit trees of all kinds may be planted with the certainty that they will grow satisfactorily during the summer. Spring planting is not equal to autumn, but still some time is saved by planting now instead of delaying it until the following autumn if the ground is in good condition, and the trees or bushes are well grown and fibrous rooted.

The soil on which trees or bushes are planted should have been thoroughly well prepared in autumn by deep digging and adding suitable material for improving it. Ground prepared now ought not to have animal manure introduced, as this will cause rank and succulent growth, which is undesirable. Heavy soil must be thoroughly broken up, adding old mortar or road scrapings to improve it. Comparatively poor soil would be greatly benefited by the addition of fertile loam. Light soil may have marl or clay introduced if of an unusually sandy character, and must be well compressed before planting.

Trees and bushes for planting should have especial care taken of the roots from the time they are received from the nursery. It does not do to let them be out of the ground long uncovered. The drying of the roots will, more than anything else, cause unsatisfactory growth if any. Remove the packing material at once, and should the roots from unavoidable causes have become dried, plunge them in water for some hours, after which lay them in a trench and cover with soil to await the final planting. Where the trees or bushes have only to be lifted and replanted in permanent positions the lifting ought to be deferred until everything is ready for the planting.

Examine the roots before planting, cutting smoothly all bruised ends, and shorten long and strong roots. Preserve every healthy fibre, spreading the whole out carefully, and cover them, from the stem outwards, with fine soil. Make firm, and stake the trees at once, which will prevent wind moving. A mulch of short manure should be spread on the surface as a means of arresting evaporation from the soil.

Pruning Gooseberries.—Gooseberry bushes require annual thinning out of the growths previous to the buds commencing to push. Close spur pruning is not necessary with bushes, which ought to be grown in a free manner, and not have the bearing wood cut away. Some of the older branches and partially worn-out shoots may well be dispensed with. Thin out the rank wood in the centre of bushes, and shoots that are inconveniently near the ground cut entirely away. The aim of the pruner must be to judiciously thin out and leave shapely bushes. On walls and trellises permanent branches are trained at equal distances. Each year the side growths are shortened back to two or three buds, forming spurs. Dead or worn-out branches must be renewed by training in fresh growths from the base.

Pruning Currants.—Red and white Currants as bushes, or trained on walls and trellises, are pruned in closely—that is, the side growths are shortened to a few buds at the annual pruning. Bushes must not be crowded with too many principal branches, five to seven usually being enough for forming productive trees.

Black Currants should be grown in a less restricted manner. The pruning of these may be confined to cutting out the oldest wood and encouraging vigorous young wood, distributed evenly over the bushes. The best fruit is borne on well-ripened young shoots.

After pruning is completed Gooseberries and Currants may be freely dusted on a damp day with lime or soot, or both combined. This will have a cleansing effect on the bushes, and also serve to protect the buds against birds.

Strawberries.—If the cleansing of Strawberry beds was omitted in autumn it ought to be attended to now without further delay. Detach the runners from the principal crowns, and then hoe or fork up along with weeds. The ground between the plants should receive a liberal mulching of manure, which does not require to be dug in, but allowed to remain on the surface.

Beds cleansed and dressed in autumn may now have the loose material raked off, and be lightly pointed over with the fork, but not injuring the

roots. It is rather early yet to give the spring mulching. Recently planted beds require occasional hoeing between the plants. If any plants have become loosened make them firm again in the soil.

Ground may be prepared for new plantations, choosing a situation not previously occupied with Strawberries. Dig deeply, preferably double-digging the site, and add good decomposed manure in liberal quantity to light soil. Heavy soil is more benefited by thorough breaking up and deeply working than shallow cultivation, even if manure is freely employed. The preparation of the soil should precede planting by several weeks, in order that the freshly moved ground may have time to become consolidated, as Strawberries prefer firm ground in which to root. Plants from nursery beds formed in the autumn are the best for spring planting, which ought not to be delayed beyond the middle of March.

FRUIT FORCING.

Peaches and Nectarines.—*Earliest House.*—Where the shoots reserved at the base of the present bearing wood are sufficiently advanced, they should be tied down, so as to give them the desired inclination, taking care not to bring them too sharply to the branches, nor endeavour to tie them until they are sufficiently advanced to allow of the operation being performed without snapping off their points. The terminal growths of leading branches should be trained in their full length, pinching the laterals to one leaf as produced. Growth for furnishing branches also require to be trained in without stopping, tying and regulating them as they advance, in doing which leave plenty of room for swelling. In laying-in young growths from extension branches, allow a distance of 12 to 15 inches between them, and about 6 inches between the shoots, so that the foliage will receive plenty of light and air. Shoots retained to attract the sap to the fruit must be kept closely pinched to one leaf after they have previously been stopped at the third joint or to that with a good leaf.

Make an examination of the border every fortnight or three weeks, not being deceived by the surface looking wet from syringing, and supply water or liquid manure to weakly trees thoroughly, whenever required. This procedure is better than having stated times for watering, for needless supplies of either water or liquid manure only tend to make the soil sodden and sour, while neglect of affording moisture retards growth and favours attacks of red spider. Syringe the trees in the morning and afternoon to keep this pest in subjection, and for it and aphides apply an insecticide, petroleum emulsion properly diluted being effective and safe. The temperature should be maintained at 60° to 65° by artificial means, a fall to 55° on cold mornings being much better for the trees than sharp firing, which only induces attenuated growths and favours insects.

Trees Started at the New Year.—These will now require attention in disbudding, doing it gradually, removing the strongest and ill-placed, retaining a good growth at the base of each current bearing branch, and a shoot on a level with or above the fruit. Thinning the fruits must also be attended to where too thick by first removing the smaller and those on the under side of the branches, but avoid wholesale thinning and disbudding, proceeding on the principle of a little and often. A temperature of 55° at night in cold weather, 60° when mild, 60° to 65° by day artificially, advancing to 70° to 75° from sun heat, and free ventilation from 65°. Syringing the trees must be practised morning and afternoon, except when the weather is dull, when an occasional syringing and damping of the paths and borders in the morning and early afternoon will be sufficient.

Houses Started at the Beginning of February.—The trees are coming into blossom, and must not be syringed after the anthers show clear of the corolla, but sprinkle the floor and border every morning and afternoon when bright, occasionally only when dull. Avoid cold currents of air, yet ventilate early and freely on all favourable occasions. Maintain a temperature of 50° at night, 55° by day, advancing to 65° or more from sun heat, but not without full ventilation. Leave a little ventilation constantly at the top of the house, and enlarge the opening on dull days so as to insure a change of air, keeping the atmosphere buoyant, for a stagnant condition of the air of the house is fatal to a good set of fruit. Attend to fertilisation when the blossoms are fully expanded and the pollen is ripe by shaking the trees, or dusting with a rabbit's tail mounted on a small stick, or a camel's-hair brush.

Trees to Afford Fruit in July or Early August.—The house for this purpose should be started early in March, there not being any need to close the house; but give air fully day and night, except when frost prevails, to prevent the trees being brought on too rapidly. Nothing, however, is gained by striving to retard the trees at the blossoming stage, but everything may be lost as regards a crop by failing to attend to the conditions essential to a good set of fruit. These are ceasing syringing after the anthers appear, and only a moderate air moisture for the proper development of the blossoms—a temperature of 50° by day, advancing to 65° with abundant ventilation, and 40° to 45° at night with enough air to prevent the atmosphere becoming stagnant. If there be a plentiful show of blossom remove those on the under side of the trellis or the back by drawing the hand the reverse way of the growth.

Late Houses.—The buds in these are much too forward where the roof-lights are fixed, there being quite a fortnight's difference between them and those which have been exposed since the fall of the leaf. All pruning and readjustment of the trees on the trellises must be completed without delay. Where the lights are off they need not be replaced until the buds show colour. In other cases ventilate freely, merely excluding frost, or not that, as the buds take no harm until they are swelled so as to show pink or red. The pruning must be completed in the case of trees in unheated houses before the buds are much advanced and swelling, and they cannot be kept too cool, as late blossoming is an important matter,

the spring frosts and dull weather at the time of setting often proving disastrous to the crop. Indeed, unheated houses are not advisable, especially in cold localities. Fixed roof-lights are a still greater mistake, as the blossoms come on too rapidly in seasons like this, and they often have to struggle with a close, moist, cold atmosphere when they should be setting. A little heat during flowering does much towards insuring a good set, and in late summer a gentle artificial warmth does much in ripening the fruit and maturing the wood. Examine the borders, making sure that there is no lack of moisture. If the soil has left the walls loosen it with a fork, and close the interstices so as to make the water go through all parts of the borders, and thoroughly moisten them from the surface down to the drainage.

THE BEE-KEEPER.

THE WEATHER.

BEE-KEEPERS are usually close observers of the weather; it is, therefore, interesting to compare notes with those who may be more favourably situated in other parts of the country. In this district (South Yorkshire) the changes that have taken place in the weather during the first month of the year have been many. The early days of January were exceptionally mild, the bees being almost daily on the wing. Afterwards high winds prevailed, causing disaster to the bees owing to the roofs or hives being blown bodily over. Rain and sleet followed, then a spell of fine weather and a high temperature. Frost afterwards set in, 12° being registered two nights in succession, and again a rapid change to rain. Similar weather has prevailed up to the present time—fine mild days, rain, frost, and snow. It having been snowing for several hours the whole surface of the ground is at the moment of writing covered with a white mantle. This will probably disappear as rapidly as it came, as the sun is now gaining power daily.

What will be the condition of the bees after the various changes in the weather? Will they have commenced breeding at this early date? After a wide experience of bees wintered in a variety of hives, we do not think they suffer nearly so much as some bee-keepers imagine if they are in dry and well ventilated hives. Strong colonies in favourable situations will doubtless have commenced breeding if the stock is headed by a young queen. It is, however, of little advantage to the bee-keeper to have brood thus early in the season, as a cold spell of weather may set in at any time, and it may then become chilled.

Bees if not handled or disturbed during the winter months, and are well supplied with stores, rarely make a mistake in this respect, as the brood nest will not be enlarged until natural pollen can be obtained outside the hive. Should the apiary be situated in a district where early spring flowers are scarce, artificial pollen must be supplied to them; but in any case the bees may be depended on not to raise more brood during the early spring months than they have food for.

HIVES.

Whilst on the subject of early breeding, it may be an advantage to know which is the best hive for wintering purposes. We should have no hesitation in saying there is nothing equal to the straw skep for this purpose, and in a large apiary we would recommend bee-keepers to always have a few skeps for early swarms. We have practised this system for many years with varying results. The stocks in straw skeps are not always the strongest in early spring. But taking one with the other they invariably winter well. The colony in a warm frame hive, if well attended to, will be much stronger by the time the honey flow comes than one in a straw skep if it does not swarm. If it does, then allowance must be made for the old stock, swarm and cast as the case may be.

A hive with double sides, or one having an open-air space which may be filled with cork dust, may be depended on to winter bees successfully. We have on several occasions experimented with a given number of hives, some of which had an inch or more of open space round the hive. In the others this space was filled with some warm material as mentioned above. There was not sufficient difference, however, the following spring to enable it to be said that one was better than the other.

Again, some bee-keepers will have the majority of their hives made with single sides without any packing or open-air space. Hives of this description are soon affected by the various changes in the weather. They, no doubt, are soon warmed by the sun striking directly on them; the extreme cold, however, will affect them in the opposite direction. They are very hot in the summer; but this may be counteracted by shading them during the prevalence of bright sunshine. We have some extra strong colonies in hives of this description at the present time, and it is somewhat difficult to say which are the best.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Anti-Blight Powder (C. D., Kent).—This preparation may be procured from Messrs. Barr & Sons, 12 and 13, King Street, Covent Garden, London, W.C.

Lettuce Culture (G. W.).—The practical article by "E. D. S.," on page 121, will probably convey all the assistance you require. If such is not the case let us know what further details you require.

Stapelia patula (G. Lingard).—We can best answer your question relative to *Stapelia patula* by reproducing an article and an illustration which appeared in our columns some years back. This you will find on page 123, and if we can further assist in respect of this or any other plant we shall be glad to do so.

Ring of Eggs from Apple Twig (Sussex).—The eggs from an Apple twig are those of the lackey moth, *Bombyx neustria*, which appears rather a common occurrence this season, especially in the South of England. For preventive and remedial measures we refer you to last week's *Journal of Horticulture*, "Eggs on Apple Twig (Medway)," page 116.

Protecting Buds against Bullfinches (W. T. F.).—The proportions of the lime and soot mixture are—equal parts by measure of quicklime, freshly burned light lumps, and recently swept soot. Slake the lime, and when fallen to a fine powder place in the soot, mix well, and then add water so as to form a thin wash that can be readily applied with a syringe. To prevent this clogging, the mixture should be passed through a hair sieve. Except for the glaring whiteness lime alone acts just as well or better. We simply procure the freshly burned lime, slake in water, forming at once into a whitewash, and apply with a rose syringe when the bushes are dry. It adheres to them, and the birds leave the buds alone. Old lime washes off, birds care nothing for it, and it has little effect on lichen and moss. We have not kept any account of the quantity of water necessary, but have used the lime, also the mixture of both soot and quicklime, for half a century with great advantage in protecting the buds against bullfinches and sparrows. Some slake the lime, then form into a limewash consistency with boiling water in which 3 ozs. of soft soap to the gallon has been dissolved, and apply at a temperature of 130°, or as hot as the finger can be borne in it. The "hot" mixture acts better on insects—the only advantage.

Birdlime (Idem).—Half the stuff made spoils the feathers of the birds. One of the simplest preparations is resin and sweet oil melted together to the required consistency, about two parts resin and one part oil. "Myocum," a substance obtainable from some nurserymen (Dickson's) answers well, and so does the "birdlime" to be had from birdcatchers, and some so-called "naturalists." The best is made from either Holly bark (the middle bark) or Mistletoe berries. The Holly should be gathered in June or July, and boiled for six or eight hours till it becomes tender; then drain off the water, and place the material in a pit under ground in layers with fern (bracken), and surround it with stones. Leave it to ferment for two or three weeks, until it forms a sort of mucilage, which must be pounded in a mortar into a mass, and well rubbed between the hands in running water; all the refuse must be worked out, then place the mucilage in an earthen vessel and leave it for four or five days to ferment and purify itself. The Mistletoe berries must undergo a similar process. It will stick to the fingers or hands of those preparing it, and may be removed by means of spirits of turpentine.

Moss on Tennis Lawn (L. S. H.).—For the destruction of the moss use one peck of unslaked lime and one peck of dry wood ashes, and distribute the mixture evenly over the surface after this has been scratched well with an iron rake, removing the moss disturbed thereby. It may be done from now to March in mild weather, the earlier the better. If a better growth of grass is desired apply a dressing of decayed manure or compost a short time after using the lime and wood ashes, or soot during moist weather when the grass begins to grow. A peck per rod is a sufficient dressing.

Asparagus for Market (A. H. E.).—The most popular and best variety of Asparagus for market work is a selection of the Giant as offered by leading seedsmen. We have had excellent results from the True Giant, it being more productive than Connover's Colossal, though this attains an enormous size. Well grown heads of the True Giant measure from 2 to 3 inches in circumference, and these splendid heads command the readiest sale and most money, as you have been rightly told. Size, however, very much depends upon cultivation, but, of course, the better the variety the more satisfactory the result.

Pruning Black Currants (Lampeter).—These bear to some extent on spurs, but not nearly so freely as Red and White Currants, therefore the bushes on walls should be pruned and trained on the young wood and spur principle combined, as in the case of the Morello Cherry, laying in some young wood annually, and cutting out a portion of the old. We should now shorten some of the young growths to a few buds of their base, and leave some of them full length for bearing. The short stubby shoots or natural spurs will give fruit, and must not be shortened, though they may be cut away when they become too long, always in favour of younger growths nearer the wall. If closely spur-pruned like Red Currants the Black produce very little fruit.

Cyclamen Bulb and Maggots (T. T. R.).—The corm has had its roots almost entirely devoured by the maggots, which accounts for the flowers not developing properly. The "maggots" are the grubs or larvæ of the grooved or black Vine weevil, *Otiorhynchus sulcatus*. They are extremely voracious and very fond of the corms of Cyclamen, often eating away the lower or under side as well as the roots. The weevils are also destructive, eating the tender fronds of Adiantums and other Ferns, and leaves of Peaches, Nectarines, and Vines. There are few worse pests, and not many harder to kill in the larval state. We have tried many specifics, and find the simplest is to water the plants with water as hot as the hand can bear for about half a minute. The worst of the mischief is that of their not being detectable until they have greatly injured or ruined the plants; we therefore make a practice of watering the plants occasionally with a weak solution of Little's soluble phenyle, 1 fluid oz. to 3 gallons of water, as a preventive, commencing towards the end of summer.

Fever Fly on Black-seeded Brown Cos Lettuce Roots (H. A.).—As you have not forwarded specimens, we can only accept your description, for the disease is certainly new to us on this plant, though we have found the "fever fly," *Dilophus vulgaris*, on the roots of cereals and grasses, and occasionally other plants. The grubs are only about a quarter of an inch in length, cylindrical, legless, dirty white, with a brownish head or "snout." They live in the roots or underground stems, and work upwards and inwards, several being found at one stem. The pupæ are chestnut coloured, and the fly two-winged. As regards prevention, a mild dressing of fresh gas lime, 1 stone per rod, mixed with an equal quantity of air-slaked lime, has been found useful. Its use on bare ground would not affect the crop taken shortly afterwards, only leave on the ground for a few days before turning under. We have also found great benefit from kainit applied in February, especially on light land, 1 ton per acre, 1 stone per rod, this heavy dressing not doing any harm left on the surface for a month or six weeks before stirring the ground or cropping. Good results on another plant resulted from the use of a mixture of bone superphosphate and kainit in equal parts, 7 lbs. per rod, applied to the surface and turned under as soon as convenient, afterwards using 1½ lb. per rod of finely crushed nitrate of soda, this being applied as soon as the seedlings were thinned. We do not think nitrate of soda alone desirable, though it certainly stupefies the grubs and they die, while the crops thrive in consequence.

Liming Vine and Peach Borders (N. D. P.).—The lime (slaked in a box by air about twelve months) may be used on the Vine border of the house to be started next week, as the lime will be quite mild, having parted with most of its causticity and passed into the carbonate condition. It then dissolves slowly and constantly in the soil, and acts on the organic matter and in turn on the other mineral constituents of the soil, besides supplying the all-important lime directly or indirectly to the Vines. As you say the soil has not a particle of lime in it, but plenty of iron, it would be advisable to use a little gypsum along with the short manure used for mulching—say, 4 ozs. per square yard, sprinkling on the surface. This will correct any tendency to sourness, and also act on the iron. We should use equal parts of air-slaked lime and soot by measure, and apply half a pound of the mixture per square yard, pointing in lightly, or that quantity of lime may be used. It can, of course, be left on the surface and be worked in by the waterings; but avoid making the border too wet by needless applications. The treatment in other respects appears excellent, the results justifying the procedure. 2, Lime is an excellent dressing for a Peach border, and the air-slaked form much the better, as, nearly reverted to the carbonate state, it will not act so energetically on organic matter, and yet yield lime slowly in solution—that is, it will be dissolved out by the soil waters and pass away by the drainage, except so much of it as the nitrifying micro-organisms have made available for taking up by the roots of the Vines or Peaches as nitrate of lime.

Old Currant Bushes (Amateur).—Those with thick main branches, spurless at the base and upwards to a great extent, ought not to be tolerated for long without some attempt being made to renew their vigour by originating new shoots, cutting the old ones away. This can easily be done by selecting a strong growth, either from the base of such above or below the ground line, or a prominent sucker springing up in a suitable position. Very old and fungus-stricken bushes should be discarded, grubbing up and burning them, then the ground must be deeply dug, sweetened, and enriched before planting young vigorous trees.

Peaches to Ripen in July (R. Lawrence).—The trees to afford fruit in July must be started at once, they having commenced to swell their buds naturally. Syringe the trees occasionally until the blossom buds show colour, when it should be discontinued, but sprinkle available surfaces once or twice a day to maintain a genial condition of the atmosphere, avoiding a close stagnant one. If the flowers are very numerous thin them by rubbing the hand downwards on the under side of the shoots, which will strengthen the remainder, enabling them to set better. Maintain a temperature of 40° to 45° at night, and 50° by day, above which ventilate freely. When the flowers expand raise the temperature to 50° at night, 55° by day, and 60° to 65° from sun heat with free ventilation. On cold nights the temperature may fall to 45°, or even less, also 50° by day, allowing a little ventilation constantly at the top of the house.

Pruning Apricots (V. S. P.).—Extreme measures in pruning are ill-adapted to the Apricot, the most successful results following when pruning can be reduced to a minimum. Apricots bear freely on well-ripened shoots of the previous year, also on spurs formed by shortening shoots not wanted for extension or furnishing young bearing wood. In addition to these, spurs are naturally formed, and wherever such are suitably placed they should be retained in preference to artificial spurs. The overcrowding of spurs should be avoided, and undue elongation of spur clusters prevented by judiciously shortening projecting portions either at the winter pruning or when the trees are examined after the fruit is gathered. The annual shoots reserved for bearing ought to have the immature points removed down to firm wood, being usually when thus shortened about a foot or 15 inches in length. Weak shoots cut in closer. Those reserved with the intention of originating new growth must also be pruned to a strong wood bud.

Apple Royal Jubilee (D. E. H.).—This variety bears a close resemblance to Golden Noble, the fruit being medium sized to large, usually very even, conical (instead of round, as in Golden Noble), skin smooth, clear bright lemon, without any flush of red, but a few small reddish spots and small patches of russet; eye small, rather closed; stalk short; flesh yellowish, firm, solid, with a pleasant acid juice, and baking of a clear amber colour, perfectly melting, and with a rich acidity. A very handsome and heavy culinary Apple, in use from October to March, but most valuable at midwinter, as conical fruit is preferred in the markets, especially golden, about Christmas. The tree has a compact but free habit, very stout and firm, is late in flowering, foliage large and shining, and the wood being stout and robust the fruit is not liable to fall in windy weather. It is a free bearer and healthy—a fine sort to graft on old stems. This Apple was raised by Mr. Graham about twenty-eight years ago, and has been grown to some extent in Kent, experienced growers regarding it as a great advance on the softer autumnal Apples, as it travels well, and can be kept until March. It does well in any good loamy soil, and though a Kentish fruit would no doubt succeed in favourable localities in the north—at least, it gives promise of sterling value further north than your location.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. (H. C.).—Your Apple is the Broad-eyed Pippin. It is a very old English variety, and was mentioned by John Ray, a celebrated botanist and writer, who was born in 1629 and died about 1704.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably

injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (S. Junior).—Begonia insignis, slightly out of character. (W. J.).—Crotons, are florists' flowers that can only be named by comparison in a large collection. The Ferns and Selaginellas were quite dead through packing in cotton wool. Orchid shrivelled, probably Lycaste Skinneri. (A. H. E.).—Apparently a small leaf of Calathea (Maranta) tubispatha.

SHEEP FOR MUTTON.

WE are well acquainted with wholesale butchers in a large way of business, men who know what is what and have either made fortunes out of their business, or we are very much mistaken. We meet with them, not every day but occasionally, and have been very much struck with the constant tenor of their remarks on the mutton trade. They have one text, "Farmers must cater for the public."

Now when these men speak of the public they do not mean the Bradford woolmerchants but the toiling millions who eat the joints of mutton. Wool is not what it used to be, an uncertain quantity,

but is now a certain quantity of very low value, and that value seldom rises; if it does so for a short period, invariably falling lower than before. The fact is that the English farmer cannot compete with his colonial brother in the production of wool alone, and to the English sheep breeder of the future wool must be more of a bye than a staple product.

Notwithstanding freezing chambers and all the newest appliances, the carriage of mutton from the Antipodes must still be an expensive process and give the Englishman a good advantage in supplying the home market with fresh meat, but the carriage on bales of compressed wool is quite another thing, and amounts to nothing on the gross value of the commodity.

Well! If the British farmer is to turn his attention to mutton and leave wool to take its chance, what do our friends the butchers say on the subject? What they want, and therefore what their customers want, is a blackfooted sheep of about 70 lbs. dead weight.

We have been much interested in an article (by a lady) in the "Nineteenth Century" for December, on "Neglecting our Customers." It was illustrative of the way in which foreign markets are lost to the producers of English goods. The facts put forward were very startling, but will it not be the same at home if the home producer does not set his house in order and prepare to hold his ground? In fact, everywhere we see goods marked, "made in Germany," "made in Bavaria," made in every nook and corner of the earth, filling English markets, and this free trade practically means the best of everything at moderate prices.

Therefore, as the British consumer is determined to have one class of mutton put on his table, if the home farmer does not supply him with what he wants, the foreigner will.

As long-wooled sheep, with their white legs and over-fat heavy carcasses, are not suited to the English market, wool must be sacrificed; and short-wooled down or mountain sheep, or better still cross-bred sheep, must take their place.

And here we find perhaps the key to success in breeding sheep for mutton purposes. As long as pure breeds only are used, almost any cross will be successful. It is strange but true, that a first cross between two old-established and pure yet distinct breeds of sheep produces an animal which for vigour of constitution, and therefore mutton-producing power, is superior to either of the two parent stocks. Constitutional vigour, the result of the infusion of new blood, displays itself in increase of bone and lean flesh; the very points which the butcher is now seeking, in order to satisfy his customers. We are told, and we believe it to be true, that this spring will have seen the birth of more cross-bred lambs than has ever been known in this country. This shows that, notwithstanding high prices for pure breeds, the farmer at large is taking advantage of his opportunity, and is making use of these breeds, lying so ready to his hand—very much, we hope, to his future advantage.

No one with a knowledge of and interest in the meat trade can have failed to notice the increasing quantity of lamb offered in the butchers' shops during the spring and summer, and how from July onwards the young animal gradually takes the first place in the supply of mutton.

This is the result of the demand for small and succulent joints, successfully met by the enterprise of farmers in forcing their sheep to early maturity. We do not much believe in autumn-born lambs; they are generally delicate, and it is rather difficult to get them fat quickly enough to make good lamb—i.e., good enough to satisfy the epicure who is willing to pay a high price for it.

Christmas or a week or two later is quite early enough to commence the lambing season, for the lengthening days and increasing hours of sunshine have much to do with encouraging the milking power of the dam and the growth and well-being of her offspring.

Ewes which lamb down early require liberal feeding during the period of gestation, so that they may be in a condition after lambing to give full scope to their milking powers. Of course there is a greater lambing risk to an ewe in good condition than to one comparatively poor; but, in farming as in commerce, to earn profit risk must be run.

It is necessary, therefore, in the first place to have the ewe in good condition, for if she be young it will not have been a difficult matter, and if she be comparatively old and intended for drafting off in the summer the extra food will be recovered in the sale of the ewe if it is not in the lamb. But it will be, for it is in the older ewes that good treatment so well repays the cost.

In the first place, when trying for early lambs it is always the old ewes who lamb down first; in fact, it is very difficult to get early lambs from shearlings. Another thing! The shearling keeps up her milk supply much longer—i.e., does not dry off so soon—but the old ewe gives much the larger supply when the lamb most wants it (if he is to be made lamb of). When the lamb has gone to the butcher at 45s. to 50s. it does not matter how soon she dries up, and makes ready to follow to the same bourne from which no sheep returns.

WORK ON THE HOME FARM.

We have had two days' sharp frost and easy manure leading, followed by drizzling rain and April-like showers. Everything is very wet, and the muck-cart, though still at work, is making a bad mess of the roads and of the land so far as it has to go.

Rolling Wheat cannot be entertained, and the cross-cutting of fallows, though obviously the next item in the farm-work catalogue, will have to be deferred until the weather is drier. It is no use turning over the land ready for working if we are puddling it with the horses' feet at the same time.

The Turnip land is ploughed close up; then what can we do but lead muck and let the District Council take care of the roads? Fortunately the land has to pay but half the cost.

We rejoiced in the short and fleeting frost as likely to create a nice mould for the Oats. Alas! the rain is sadly spoiling our hopes, and we must not attempt any preparation for sowing until the weather takes up, as one day's heavy rain can undo all the previous day's labour. Herein lies one of the chief advantages of a large farm and a good force of horses, in that a day's drilling, say 12 acres, can be prepared, drilled, harrowed, and, weather permitting, rolled down in one day, and as it were, at one operation. If rain comes on during the day but a small portion of the labour is wasted, the several implements following each other closely.

We hear of a few early lambs, but have not seen any as yet. Ewes require well feeding now until they lamb down. Swedes are not a suitable food just before lambing; we find Mangold given on grass the most healthy food. There is little difficulty in lambing, and the ewes milk well.

It is a good thing for ewes to have a walk of half a mile or so to and from the lambing pen, the exercise does them a world of good. We have known a flock taken from the fold to a field of Turnips more than a mile away, and though two or three might be wisely left at home by the shepherd in the morning, the general health of the flock benefited greatly by the exercise.

We see that the Queen's speech promises great things to Irish farmers; we hope that they may find some more substantial fulfilment of the goodwill than English farmers have.

REMARKS.

- 5th.—Rain from 4 A.M. to 10 A.M., dull and overcast after.
 6th.—Overcast morning; heavy rain and sleet from 3 P.M. to 7.30 P.M., and drizzly after.
 7th.—Dull and drizzly till 10 A.M.; bright sun from 11 to noon, and occasionally after; thunder and spots of rain at 3.35 P.M.
 8th.—Heavy rain between 2 and 4 A.M., then overcast till 11, and the remainder very wet.
 9th.—Shower at 4.30 A.M.; overcast morning; heavy rain from noon to 3.30 P.M.; fair night.
 10th.—A lovely spring day; the warmest in February for more than forty years.
 11th.—Fine, and sunny at times in morning and afternoon; but rain from 0.30 to 2 P.M.

A very warm and wet week.—G. J. SYMONS.

A FEW SPECIALITIES.

- Barr's Monstrous Long Pod Broad Bean.**—The earliest, best flavoured, largest podded, and most productive. Per quart, 2/6.
- Barr's Green Haricot Dwarf French Bean.**—Of very delicate flavour, and unsurpassed as a Haricot Bean in Winter. Per quart, 2/6.
- Barr's Best of All Autumn-cutting Cabbage.**—Dwarf and compact, very early and of exceptionally fine cooking quality. Per packet, 6d.; per oz., 1/6.
- Barr's Earliest French Short Horn Carrot.**—A favourite for soups, and extremely early; the best variety to sow in frames. Per packet, 4d.; per oz., 10d.
- Barr's "Pride of the Market" Cucumber.**—A specially fine dark-green variety of handsome shape; a favourite in Covent Garden Market. Per packet, 1/6.
- Barr's Long Keeper Onion.**—A fine handsome Onion, and a very long keeper. Per packet, 6d.; per oz., 1/3.
- Barr's "First of All" Radishes.**—Scarlet or white, fine little, short-leaved, very early Radishes. Per oz., 6d.
- Barr's Early Ruby Tomato.**—Bright scarlet solid fruit of fine form; an abundant cropper; the best FIRST EARLY Tomato. Per packet, 1/-.
- Barr's Thick-fleshed Tomato.**—Surpasses all other varieties for depth of fruit, solidity of flesh, high quality, and heavy cropping. Per packet, 1/-.

BARR'S SEED GUIDE (Free) contains a full descriptive List of the best Vegetables and most beautiful Flowers, with many Practical Hints on Culture valuable to Gardeners, Amateurs, and Exhibitors.

NURSERIES: LONG DITTON, SURREY.

NOVELTIES

RAISED AT

WINDSOR AND OSBORNE.

It is Messrs. CARTERS' privilege to offer the following new and choice productions to the notice of gardeners and private cultivators.

BRITISH QUEEN MELON.

Raised and named by Mr. OWEN THOMAS, Supt. of the Royal Gardens, Windsor. Awarded the First-Class Certificate R.H.S. Pronounced by the Committee to be not only the very best white-flesh melon ever submitted, but the richest flavoured of any colour. Awarded the Gold Medal of the Royal Caledonian Society in association with other fruit exhibited by H.M. The Queen.

In sealed packets, price 2/6 and 3/6 each, post free.

ROYAL OSBORNE CUCUMBER.

A valuable cross between the Rochford and an improved type of Telegraph, raised and named by Mr. GEORGE NOBBS, Head Gardener to H.M. the Queen at Osborne. In our opinion it is one of the best all the year round varieties introduced in recent years.

In sealed packets, price 2/6 & 3/6 each, post free.

ILLUSTRATED CATALOGUES, POST FREE.

WE HOLD THE ENTIRE STOCK OF SEEDS OF THESE TWO NOVELTIES.

CARTERS,

The Queen's Seedsmen.

Only Address—

237, 238 & 97, HIGH HOLBORN, LONDON.

Journal of Horticulture.

THURSDAY, FEBRUARY 23, 1899.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

SCIENTIFIC KNOWLEDGE.

A Primrose by a river's brim,
A yellow Primrose was to him,
And it was nothing more.

"AN ounce of practice is worth a pound of theory." How often these words have been thrown out as an unrefutable argument in favour of rule of thumb or empirical knowledge alone! It must be admitted they are difficult to answer, because the statement is true up to a certain point. What is meant is that practice alone is better than theory alone, and this no one will deny in matters horticultural. Can we, however, go so far as to say that theoretical knowledge is absolutely useless?

Those who object to scientific teaching as worthless or are carried away by their prejudices against such instruction—even in some cases considering it absolutely mischievous—either do not know, or have not considered seriously, what is meant by it. With the best of intentions they speak disparagingly of this kind of teaching, regardless of the fact that (to quote Smiles) "though many of these facts and observations seemed, in the first instance, to have but slight significance, they are all found to have their eventual uses, and to fit into their proper places." We all admire the "practical" man, but if we consider seriously we must acknowledge that he is brimming over with theoretical knowledge—in many cases obtained through great tribulation—much of which could have been obtained by the study of reliable books.

We are aware there is a great improvement in recent years, but with the development of glass culture which has made such immense strides during the last decade, there are hundreds of workmen engaged in horticultural pursuits who have no acquaintance with the facts in science connected with their occupation. They are mere machines, hewers of wood and drawers of water.

Then, again, there are the small nurserymen. Many of these are striving their utmost to make

3 CROSS LANE, LONDON, E.C.

both ends meet, and yet owing to the lack of technical knowledge they expend on manures far larger amounts than they would if they knew the requirements of their plants, and how to proceed in supplying them; or should a fungoid or other disease appear they are perfectly helpless, and have to solicit advice from the nearest scientific neighbour.

The rule-of-thumb man sails comfortably in smooth water, but he is "all at sea" when the storms of disease and difficulty assail him. A workman who is educated and possessed of the necessary grit, is in every way more useful to his employer, and is himself a more intelligent, and therefore a happier and a better man. He will, as a rule, be distinguished by superior moral habits in every respect, sober and discreet, and indulge in amusements of a rational kind. The ignorant workman drops his tools and thinks no more of his work until the next morning; the intellectual man in his spare moment devises and schemes plans, which improve his own work and benefit his employer.

There are few branches of scientific knowledge that will not throw a strong light on all we do in the garden, in the nursery, or on the farm. "Science" is what we know to be true, what Professor Huxley, I believed, called "organised common sense." It can be proved, for instance, that ten elementary substances are essential for the growth of a plant. Deprive it of one of them and it languishes and dies. Would it not be advisable for all who cultivate plants, either for pleasure or profit, to become acquainted with these elements, and to know whence they are derived? This would be learning what is termed "science," and the particular branch known as "chemistry." How many there are who yet view all the different objects of Nature with comparatively blank mind as to their construction and components, yet every hedge and ditch, every seedling and plant, every flower and herb, every pond and brook, becomes a centre of attraction, a new world to us, when science reveals to us Nature's charms.

Let us begin with some simple work on botany. The poet Wordsworth tells us that to one of his characters a Primrose was a Primrose—and it was nothing more. Yes; and we may venture to say it is nothing more to scores of our young men of the present day. Would it not be well to study the wonderful device the Primrose has for insuring cross-fertilisation, or the marvellous arrangement for the preservation of the nectar from all insects which would rob the plant without in return doing it a service?

Again, light and heat are two of the phenomena of Nature intimately connected with plant growth. An easy work on these subjects would enable many a man, if he had thoroughly assimilated the contents, to ward off accidents that happen through defective ventilation or too great an exposure to the sun's rays.

Geology takes us back into remote ages, revealing to us the flora and fauna of a world otherwise unknown to us. It acquaints us with the history of the soil—that immense storehouse of plant food and chemical laboratory in which some of the most wonderful changes in Nature take place. It teaches us that the work of Creation is still going on—that new continents, and new varieties of rocks, and soils, and plants, and animals are continually being evolved. It explains why we find sandy soils in one district, clay in another, and chalk in another.

Biology introduces us to the life which is invisible without the assistance of the microscope. It reveals to us the mysteries of the vegetable cell, the eelworm and the Potato disease, the mildew and the damping-off fungus. Every gramme of soil and every drop of impure water teems with life, much of which is of great importance to the cultivator of plants. We hope that enough has been said to induce more of our young gardeners and nurserymen to make a start in acquiring scientific knowledge. We cannot be certain that it will enhance their position, though this is more than probable, but we may be sure it will increase their own happiness to no small extent.—F. S. H.

HARDY FLOWERS IN FEBRUARY.

FICKLE has been the weather since the dawning of the year. The fate of the outdoor flowers has been a hard one. Under glass their kindred have enjoyed the heat and shelter while they have borne the cold, the snow, and the rain. They have had all three. The frost in the North has been keen, and they have withstood it without a protecting covering of snow for days. At length Nature's shielding mantle was laid over them, and then came rain and swept it away. As this is being written there is every appearance of the frost having gone for the time, but at this season it is unsafe to attach much value to weather signs.

We cannot expect many flowers in the garden now. There are fewer than we often have at this season. "Rain, rain," was the burden of the dying year; "rain" again that of the new, followed by intense frost. Surely nothing could come into bloom and remain with such a time. Yet there are a few flowers, and these we may wander out to see. Even the Snowdrops are, as a rule, late. Our Fair Maids of February may have opened in time for their anniversary day, February 2nd, old style, but they have not anticipated it, though some of those allied to *Galanthus nivalis* have come before. But now they are around us. With pure blossoms they swing in the breeze. Of various sizes and with slightly different form they delight us with their grace and their sweet beauty. "Fair-handed Spring" has many brighter, but no fairer flowers than these blossoms sent, as the legend says, to comfort Eve when driven from Paradise.

Linked with the Snowdrop, in Thomson's poem of "The Seasons," is the Crocus; it is associated with it in our gardens too. Not yet do the clumps of the great Dutch Crocuses enamel the ground with their vivid colours, but there are some of the race to forewarn us of their coming—some whose beauty, if less brilliant, is no less pleasing. Delightful are those clumps of *Crocus Imperati*, whose fawn and black spirelets unfold in the sun into flat saucers of bright purple. If less brilliant, pretty are these little flowers of *Crocus Sieberi*, which, as if to compensate for its lesser brilliancy when open, is bright purple-blue when closed, opening almost the same hue when the sun lights upon it. The little *Crocus ancyrensis* has not quite disappeared for the year, but it has been eclipsed by the larger blooms of *C. aureus*, which in the border and rock garden glows even in the rain, as if the sun were shining with its utmost fervour.

In the rock garden bushes of *Erica carnea* are ruddy with their waxen blossoms, which, though they have not assumed their perfect colouring, are yet admired of all. Beautiful as is the white variety *E. c. alba*, and more nearly as it approaches the "lucky" white Heather of the Highlands, it is the pink which is generally more admired, with its perfectly coloured and formed little flowers. In sandy peat in the rock garden it is quite at home, while in beds or borders it is almost equally happy.

Not many of the Primroses or Polyanthes have favoured us with their flowers as yet. In few seasons have we had so great a shortcoming of winter blossoms on these favourite flowers. They might have had a premonition of what was before them if they had ventured to bloom. We miss them, though, with their varied colours and hues. The garden is the duller for their absence when we have become accustomed to their bright flowers. Even the double white Primrose, so profuse a bloomer, is unusually unkind, and is only giving its flowers as it were grudgingly. By-and-by it will strive to atone for this by profuse flowering.

Hepaticas, also, are less prolific of early flowers than is their wont. A few there are, and among them one on a double mauve variety distinct from the double red and double blue we all know. There are more varieties of double Hepaticas than most people are aware of. They are, however, difficult to obtain because of their slow increase, and because of this it does not "pay" the trader to take them up for profit. It is to the amateur that we have to look for new varieties of these. If a few enthusiasts who have time and space would work them up and raise seedlings by the thousand, we would in a few years time have something to show in the way of improvement of this old-fashioned and favourite flower.

In many gardens now we see what has been done among the Hellebores by seedling raisers. Lovely are some of the Lenten Roses, which, as hardy as any flower we have, only want a good strong soil and a half-shaded position to produce their flowers. With them improvement has gone on apace. Deep purple, bright purple, pink, almost blush, white, are the blooms of many, some being exquisitely spotted. Some of the white Lenten Roses are as pure as those which under the name of Christmas Roses are earlier in the year so highly prized. Daffodils are on the way, and soon *Narcissus minimus* and *N. cyclamineus major* will be in full bloom.

But we may bring this tale to a close. It is not a cheerful one. We cannot make bricks without straw, nor is it easy to be jubilant

when one is longing for sunny days and smiling flowers. Yet a thread of gold runs through the web of the season's trial. It meets our eyes now and again, and gladdens us because it reveals the truth that all is not dark and hopeless.—S. ARNOTT.

LONDON GARDENS OVER FIFTY YEARS.

No. 4.

ROSE-GROWING, in the open ground of gardens about the central districts of London, was a disappointing business half a century ago, and had been such, indeed, after coal became the main fuel of the metropolis. It was when wood kept up fires that the Temple Gardens displayed their memorable red and white Roses, while the grounds of Ely House yielded these flowers by the bushel. Varieties of the Provence are said to have been the last that flourished near the City. Persons have got specimens of the *Rosa gallica* to flower amid smoke, and a venerable Perpetual may be seen yet in some suburban garden, which has grown accustomed to the London atmosphere. Hedges in the semi-rural suburbs might formerly have been seen skirting the gardens of villas, with *Rose canina* shoots spreading over the Hawthorn bushes, but hedges have had to yield to walls or railings, as affording more protection. Occasionally there might be found in a London garden a specimen of the Clove-styled Dog Rose (*R. systyla*) which grew wild early in this century near Clapton and Hornsey, also in other places. It was transplanted to gardens because of its fragrant pinkish flowers, being in growth a slender species, but, under favourable circumstances it would reach the height of 10 feet.

Nothing probably can be brought forward more indicative of our progress in horticulture than the position which the Chrysanthemum now occupies amongst London flowers, for it is as largely grown both in houses and out of doors, valued specially because it keeps in bloom at a season when other flowers are scarce. Nor do the plants seem to be so sensitive to a city atmosphere at its worst as many favourite species are. This has been proved by the continued and successful cultivation of the flower in the Inner Temple Gardens. From all parts of London, fifty or sixty years ago, folks came to see Mr. Broome's autumn show, very creditable to him, but, of course, greatly surpassed by the recent exhibitions in the same grounds. Here and there a suburban garden had its bed of Chrysanthemums and Pompons. As a boy I remember visiting sometimes an old gentleman who had one of those gardens at Chelsea, common then, which were large for the size of the house to which they were attached. About half his space he had filled with Gooseberries and Currants, the other half was all devoted to Chrysanthemums. Pot culture of the plant was then in its infancy; gardeners were finding out how needful it was to protect choice kinds from wind and weather, also that many could be advantageously dwarfed. The Japanese sorts do not appear to have been known in Britain till 1870, but they stand first in popularity, and are most prolific in new varieties, perhaps seventy or eighty yearly. Hence we hear little now about the quilled, tasselled, Marigold, and Aster flowered, and other varieties our fathers thought charming. Some folks talked of a Chrysanthemum centenary in 1890, but others have tried to make out that the Chinese Chrysanthemum was unknown till 1818. Yet London, in his "Encyclopædia" of 1824 refers to it as a plant long familiar; in fact he names 1764 as the year of its introduction, though I think this date is doubtful.

The National Chrysanthemum Society held its fifty-second annual shows last autumn, the first, and other early ones, being on a very different scale to those which have for many years been so attractive. According to Mr. Dean, the indefatigable Secretary of the above Society, the principal new varieties come from France and America, few from Japan. If the ideal of a Chrysanthemum be its perfect shape, symmetry, and constancy in colour, the Japanese seldom approach this standard, and we shall award the palm to examples of the incurved, reflexed, and Pompon types. Somebody has said that the romance or poetry of horticulture lies in sowing seeds, not knowing what curious varieties may arrive which would apply to Chrysanthemum growing as to other plants which sport. Of course, out of the thousands shown at the Royal Aquarium, a large proportion come from a distance, but the suburbs of London are well represented both by cut blooms and pots.

Again, looking at exhibitions more local, we may refer to the annual show of the Highgate Chrysanthemum Society, which could draw 360 exhibitors last year, and to that of Waterlow Park, one of the best near London. Or, going southward to a poorer neighbourhood, as instancing a love for this flower amongst busy workers at the East End, we see an encouraging advance in last year's show of the East London Horticultural Society. Ten years ago, when a start was made at the People's Palace, the bulk of the exhibits came from West London; now the East-enders, though they receive friendly help, could really manage the show by themselves, so much skill have they acquired in gardening.

It has been proposed to supply young people with plants at the rate of a penny each, these to be thereafter produced, and prizes awarded to the best grown, which is a good scheme.

Glancing back, again, we can recall the fondness with which Londoners, when Chrysanthemums were few, cherished their Michaelmas Daisies, sometimes even forming a hedge of them between gardens in a row. A gawky, straggling plant, it has been called; yet there are some good varieties, and it will flower even in the air of a crowded city. It might have been seen giving a temporary cheerfulness in autumn to one of the old London churchyards, companioned, perhaps, by a sickly Guelder Rose, or a mournful Elder bush. In 1848, interments still took place within churchyards that had become dangerous nuisances, so slow are we to abolish evils all too obvious. It was no wonder that cholera should ravage many districts in 1848 and 1854; instances had even occurred of sheep being poisoned that were fed upon the unwholesome grass some produced. Many became resorts of the wandering cats of the neighbourhood, and it was not unusual for the garden portion of a burial ground to be cleared of weeds but once in the quarter. At length, in 1853, an Act of Parliament enforced the closure of all churchyards. But this did not quite remedy matters; there arose a danger that some would be built upon, converted into builder's yards, or otherwise desecrated, and, indeed, before very long had elapsed after burials ceased, not a few became repositories of all sorts of rubbish from the streets around.

Slowly it dawned upon the minds of sensible persons that places closed to the dead might be opened under altered conditions to the living; hence the movement, so fruitful in result, for the transformation of disused churchyards into pleasant gardens. Probably it was quite as well that a number of them were left alone for years, before any disturbance of the ground took place, which might otherwise have been mischievous through the diffusion of noxious gases. At least, I remember well my visit to a large suburban ground at Chelsea, while in process of conversion by extensive digging, and the experiences of eye and nose and mouth were painful.

Instances there are, however, of a burial ground becoming a garden or public resort without the removal of the monuments and stones. For example, there is the largest open space within the East Central District familiarly known as Bunhill Fields, which is in extent about 6 acres. For a long time it was the great burial ground of Dissenters; then it became the property of the Corporation of London, who spent £3000 upon it and made it free to the public; but we cannot call it a garden. Four of the London churchyards, as Mrs. Basil Holmes remarks, occupy the position of pioneer gardens. One of these is the historic little plot, only a quarter of an acre, in the midst of Drury Lane, which was a garden till, it being impossible to preserve the plants, it was turned into a gymnasium for children. Another is St. Botolph's, Bishopsgate, opened about 1876, but afterwards closed for some years. It is singular that the City has four churches named after this worthy, and all their yards are now public gardens. Right in the City's heart that of St. Botolph's, Aldgate, is wonderfully attractive though small in size. It was laid out by the Metropolitan Public Gardens Association. In May, 1892, it was opened by the Hon. Sir Charles Freemantle.

Then there is the churchyard of St. John's, Waterloo Road, noticed, no doubt, by some of the many thousands who travel on the South-Eastern line between Charing Cross, Cannon Street, and London Bridge. It was opened in 1877, and has several good trees, Elms, Limes, and Planes. I believe, indeed, a few years ago someone asked a scientific journal how he might establish a rookery there. The difficulty would be, probably, how the birds should get food if they settled in such a place, there being no fields near in which they could forage. Replying to a similar question, perhaps half in joke, an editor suggested the placing of a number of old birch brooms in the trees, so that rooks brought there might suppose it a deserted settlement.

The garden of St. George's-in-the-East is a memorable one, and has afforded enjoyment to myriads of young and old for full twenty years. We have a graphic description by the Rev. Harry Jones, of the trouble he and his friends had in obtaining leave to lay out the ground as a garden, adding to it the Wesleyan plot adjacent, which makes the whole extent three acres, a great contrast now to what it was in 1850—"a dark and clayey cat walk," so "Household Words" described it then. During summer the beds are full of flowers, and when I visited it in July many white butterflies were on the wing, to the joy of the children, if not to that of the gardener. Lastly, amongst the pioneer gardens we must mention the important one of St. Pancras, a slice of which was taken by the Midland Railway, which has recently threatened another portion. A hundred years ago St. Pancras was only a village church, but time has surrounded it with busy streets. With the addition of an old burying-ground of St. Giles's, this St. Pancras garden contains nearly seven acres, and is much frequented. One of its peculiarities is a "dome" and "trophy," composed of hundreds of headstones; elsewhere I have seen fragments of them formed into rockeries.—J. R. S. C.

CLASSIFICATION OF INCURVED.

I would like to again call attention to what can only be considered an unfair proceeding on the part of the Classification Committee of the N.C.S. A list of varieties which have recently been classed as incurved has been issued to all affiliated societies with a request that these societies insert this list in their schedule of prizes. I have since received several schedules in which it is stipulated that only the varieties classed as incurved can be shown in that section. This new list issued by the N.C.S. contains novelties which few have seen or even heard about; one is not to be sent out until the season 1900. Two varieties which should have been included are omitted, thereby deterring them from being exhibited at many of the most important exhibitions. I am referring to Lord Coleridge and Major Matthew. The first named has been before the Floral Committee several times, and has twice been returned with the request "to see it again." No doubt has been expressed as to its being a true incurved. The other variety was certificated by this Committee on the 21st October, and has also received an award of merit from the R.H.S., whilst the whole horticultural press has commented favourably on it. Is it not remarkable that whilst unknown novelties are cited a certificated variety is omitted?—W. J. GODFREY.

SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE annual dinner of this Society was held in the Masonic Hall on Saturday evening, the 18th inst., when about a hundred members, patrons, and delegates were present. W. A. Milner, Esq., J.P., the President of the Society, occupied the chair, and was supported by Mr. H. J. Jones, Mr. R. Stewart, Mr. Saml. G. Harrison, Mr. F. W. Littlewood, Mr. S. W. Seagrave, Mr. W. Housley (Secretary), Mr. John Haigh, Mr. T. Nicholson, and Mr. N. Tunnicliffe. The time was unfortunate in respect to many of the Vice-Presidents and patrons, from whom letters of regret of inability to be present were read. Kindred societies sent a dozen delegates. The usual loyal toast was given by the President and duly honoured.

The toast of the "Kindred Societies and Visitors" was proposed by Mr. John Haigh, who gave all a hearty welcome to the dinner, and expressed pleasure on behalf of the Society at the good attendance of representatives. It was ably responded to by Mr. W. Nicholson (Wakefield Paxton Society), and Mr. T. J. Nelson (Chesterfield Chrysanthemum Society). "The President and Vice-Presidents" was proposed by Mr. F. W. Littlewood, and responded to by Mr. W. A. Milner in a kind and genial manner; he spoke in very high terms of the Society's work, and the manner in which, he could say from experience, it had been conducted. "The Sheffield Chrysanthemum Society" fell to the lot of Mr. H. J. Jones (London), who said the first time he visited Sheffield on its account, he thought what a dull, miserable place he had come to; but as soon as he became acquainted with a few officials and members, all the dullness vanished, and brightness and cheerfulness appeared in its place; and now he looked forward with pleasure to every visit he paid the Society, whose progress he had watched for some time past. He wished the Society continued success, and thanked the officials for their kindness to him on the occasion of every visit. Mr. W. Housley (the Secretary) responded to the toast, and briefly reviewed the history of the Society and its rapid development. In 1885 the cash taken at the doors of the exhibition was £29. In 1898 the amount had reached £174. When the National Chrysanthemum Society held a show in connection with the Sheffield Society in 1887, the gate-money was £90. In 1885 the number of members was comparatively small, now there were almost 300 members on the books.

The toast of the "Nurserymen and Non-competing Exhibitors" was proposed by Mr. P. T. Barton, who thanked them for their past assistance. Mr. John Artindale suitably acknowledged the toast.

The toasts were interspersed with songs, which made a most excellent and enjoyable musical entertainment.—J. H. S.

CHRYSANTHEMUMS IN VASES.

FROM the report of the meeting of the Executive Committee of the N.C.S., page 121, I note a class for Chrysanthemums in vases of twelve varieties has been included in the programme for next season. Each vase is to contain *five* blooms, of each variety. Surely such difficult conditions must limit competition; this is not what should be encouraged. Five blooms of any one variety, especially if it is new or scarce, is a large order on one day. I fail to see how we are to have the best varieties included in an

exhibit that is hampered by such conditions. Evenness of bloom is especially a point to be aimed at by exhibitors in a class for vases of Chrysanthemums, and the appearance of a vase containing four good blooms and one rough will not be improved by the inclusion of the latter. This is often a necessity if some particular variety is to be staged. Far better have a class with easier conditions and praiseworthy exhibits. Keen competition and high quality are, or should be, the aim of the executive committee of any society.—E. MOLYNEUX.

MR. WELLS' CHRYSANTHEMUM BOOK.

THE able grower and energetic chrysanthemumist of Earlswood sends us a copy of his revised edition of "The Culture of the Chrysanthemum." It is a clear and practical exposition of the author's methods of procedure in raising and growing healthy plants for the production of superior blooms and for decorative purposes. The various details as carried out by Mr. Wells are narrated in a manner that can be easily comprehended, while some errors to be avoided are also pointed out. Several photographic illustrations show how well the plants are grown; insects—friends and foes of the Chrysanthemum—are also depicted, and the "rust" in different forms illustrated. Mr. Wells in combating this enemy relies on periodical syringings with a mixture of an ounce of soda and half a wineglass of paraffin in 2 gallons of lukewarm water, starting with the cuttings. The book comprises upwards of 100 pages, both paper and printing being alike good. There appears to be no extraneous matter to divert attention from its usefulness, and the issue is altogether a creditable production.

THE EGYPTIAN.

MR. WILKINSON (page 108) takes exception to this Chrysanthemum being classed by me as a poor type of an incurved bloom. I fear he has little chance of convincing the general body of cultivators that it is a typical incurved bloom unless he brings much more support into his argument than he has yet done. The variety was introduced in 1896 as a Japanese incurved. I am not certain about its origin, but Messrs. Nathan, Smith, & Son, the American Chrysanthemum raisers, described it in 1896 as a Japanese, as did Mr. Wells in the same year. Mr. Jones and Mr. Godfrey, in their 1897 and 1898 lists, class it as an incurved, but both are careful to advise growers to allow the plants to carry more than the orthodox number (three) of blooms, possibly because they fear it would betray its true character under the ordinary method of cultivation.

The fact of The Egyptian being so conspicuously absent from competing stands during the last two seasons is a sufficient proof to me of what cultivators generally think of it. Exhibitors are not slow to appreciate a desirable variety. Mr. Wilkinson must present higher credentials for his protégée than he has done before it meets the approval of growers generally, and especially of—SADOC.

LATE CHRYSANTHEMUMS.

IN reference to the note on page 112 I see no fear of the reign of the autumn queen waning. The production of huge flowers may decrease, but for home use and decoration I fail to see what can to any extent replace our old favourite. The demand, to my own knowledge, increases, both for quantity and a lengthened period of flowering. Leaving out what are known as summer flowering Chrysanthemums, the season may be said to commence in October and continue well into the new year. This is the time during which we, with not the best of means, manage to supply plants and cut flowers, while others prolong the season still further.

I can remember when Ethel and Guernsey Nugget were standard varieties for late flowering, and I believe the former is to some extent in use still in some market establishments; they were good and useful, but are now in a great measure superseded. Those we mainly rely upon for late use are W. H. Lincoln, Etoile de Lyon, Princess Victoria, and L. Canning. Boule d'Or I have found helpful grown on terminal buds. Challenge is not free, but is of a bright colour. Princess Victoria, L. Canning, and Boule d'Or are propagated when the general stock is inserted, and W. H. Lincoln and Etoile de Lyon about the end of February or beginning of March. They then, as a rule, flower together, giving us good results in midwinter, when the November plants are things of the past.

The cuttings are rooted in 3-inch pots, and receive the usual repotting and staking as needed, until the final move into 8 or 9-inch pots has been reached. We pinch out the points of the shoots of W. H. Lincoln and Etoile de Lyon once, but the others are allowed to grow naturally. It is customary to give Chrysanthemums as much light and air as possible after housing, but late plants demand still greater care and provision made for them in these respects. During October they are placed under protection at night when there is danger of frost, and in November are taken in every night and turned out every morning. The trouble is repaid afterwards with clean bright flowers.

One of the causes of the buds of late Chrysanthemums going blind is, I think, that, the feeding for the main stock being over, the remainder are sometimes neglected. This should not be; all the help possible ought to be given to bring the flowers to perfection at the most trying period of the year. There are, of course, other varieties which may be employed. I have merely named those which we have found of the greatest service.—J. SHALFORD.

DEATH OF THE REV. A. HEADLEY.

ON the morning of Wednesday, February 15th, passed away, after exceeding the allotted span by three years, the Rev. A. Headley, whose writings over the cognomen of "Wiltshire Rector" have endeared him to many readers of the *Journal of Horticulture*. His was an ideal life, though accompanied of late by pain and suffering—patiently borne, and his end is peace. He has gone whence none returns, and the day will never dawn when his memory shall have faded from the minds of men. To those who had the pleasure of personal acquaintance he was a valued friend, as was he to those who knew him by his writings alone. Through the medium of these pages, which he adorned—as it is given to few men to adorn them—he made many friends. His steadfastness of purpose, his innate charm, his geniality, and his fascinating personality placed him amongst the foremost of men, and we must now, with melancholy regret, assign him a position amongst the illustrious dead—illustrious in his purity of soul and his love of Nature. To all his friends the knowledge of his death will bring a wave of sadness and a flood of memories of the past, and these may find some satisfaction in seeing his portrait, which was taken in 1884—fifteen years before the end.

His son, the Rev. A. A. Headley, writes:—"My father had a bronchial attack, and apparently recovered from it, on Sunday, the 12th inst., but on Monday had a seizure from which he never really rallied. He sank most peacefully, and painlessly (we believe). He was the son of a doctor in the Fens, and there he got his love for bird life, which lasted to the end. He was at Corpus Christi College, Cambridge, and began his clerical life as a curate in Sussex, but from 1856 to 1890 was Rector of Hardenhuish, Wilts, where all his 'Wiltshire Rector' papers were written. He originated in one of his new year's addresses the phrase "Our Journal," and that was his loved term for the *Journal of Horticulture* to the end. He had many warm friends through it. I think he wrote for the Journal as early as 1864, and I know what a joy it was to him. No one must think the work of the village suffered. He was a model country parson, and a father whose memory will ever be green. He was buried in the churchyard here (Porchester). It was his own wish. He had a great horror of being moved a distance, and used to say, 'Where the tree falls, there let it lie.' Some might think that he ought to be in Hardenhuish churchyard, but I think it is better as it is. He came here in 1890, when he had the seizure which compelled him to resign. He liked the place, and the people were truly friends to him."

It was in the year 1864 that the deceased, in a charmingly written article, first used the expression "Our Journal," which years have made more and more popular. It will not be out of place now to show the sense in which it was employed on its inauguration.

"Now for 'Our Journal.' What a pile of them! How soon a man gets interested in a periodical! Just, and only just, two years ago I saw a number for the first time in a gardener's cottage (fit place for a 'Cottage Gardener'), and now I look forward to Wednesday's post, and cut the Journal open quickly, and know the different styles of the writers, and read my own articles."

Writing "A Few Words to all Our Friends on the New Year" in 1869, "Wiltshire Rector" said:—Gardening ever claims, and rightly, our first thought and attention. Our gardens cheer and comfort us. "In single and married there is but little difference," said Jeremy Taylor, "single life is solitude, married life is solicitude." I accept the definition, and I ask, Are not gardens and works on gardening companions of solitude and cheerers of solicitude? In countless instances they are both. Single life and gardening have gone together in all ages. The Essenes were great gardeners, so were the monks and nuns of the middle ages, and so, according to Mr. Hepworth Dixon, are the interesting celibates of the New World, the American Shakers. As to a garden being a solace to the man full of cares, notice how often you see grave-browed, city-looking men in omnibuses bound for the outskirts of London with plants on their knees, telling of villa gardens delighted in and giving delight. I have looked at such men and thought what a comfort your gardens are to you, my friends, and your wives know it too, and if they are wise they coax you to take a stroll with them in your garden, when (that trial to husband's patience) dinner is late.

Let me drop a word of advice to young beginners—the young lads into whose hands this paper comes after their seniors in the garden have read it. Visiting recently the Orchid houses and pineries in a noble garden, I asked the intelligent head gardener how he got on with the young lads under him, to whom he must confide a good deal of work, although if they failed or exceeded in duty, he would have to bear the blame. His answer was, "I get on with them very well, if they come to me knowing nothing, and confessing they know nothing; but if they fancy they know something when they really know nothing, they give me a world of trouble. I have now a couple of lads who came to me quite ignorant, and good lads they are, for they are willing to learn, and simply carry out my plans to the letter, and to please me, and will make good gardeners."

Young men! be willing to learn, watch, read, take pains, and do not presume to know before you do know. In the highest things it takes often half a life to understand our own ignorance.

Science readers! I hope this year you will turn to our pages and find the needed information. Practical readers! I hope you will do the same, with the same result. General readers! I hope many papers this year will be so written as to catch and interest you, and that the whole tone of our pages will elevate all. A bookseller said to me, unasked, "A gentleman gave up taking *The Journal of Horticulture* at the end of the year, but came to me in February, and said, 'I must have that publication again, I miss it, and cannot get on without it; it seems wanted by all of us, so send it to me.' I hope this is a testimony that we writers do not labour in

vain. As to my own experience, this expression has been in constant use among us in our house for years, "Our Journal never brought anything but happiness to our home." And much reason have I to use that expression when I sit by the winter's fire, and count the long roll of friends made by means of its pages. Perhaps much of the pleasure our readers feel arises from the fact of the undying love of nature which is at the bottom of every heart, and which only wants cultivating. And of all nature the lovely flowers stand next the heart, they look up, and are close to the eye of the child, who falls in love with them at once, and they entwine themselves around the heart of the old man and woman. The love of flowers in some hearts dawns very early, in other circumstances draw it out, but in all cases it is, love me once and love me ever. Said a clergyman, "The love of flowers came to me in trying to please the taste of my delicate wife. I took the cuttings under her guidance, and to spare her strength, and to please her; then I watched their progress, and so on from one thing to another, and I loved the flowers, first for her sake, then for hers and their own." The love of Nature is sometimes marvellously great. Thus you who know old London will remember a narrow, close, half-stilling street, called Little Tower Street; in that street, says Peter Cunningham, Thompson composed his poem of "Summer."

Such are examples of the work of a man whose hobby was Nature. The words golden then are golden now, and may advantageously be read by everyone to-day, more particularly perhaps those referring to the rising generation. The sentiments therein expressed might well have been written especially to the members of the "Young Gardeners' Domain."

RECENT WEATHER IN LONDON.—The fog that enveloped the southern suburbs of the metropolis on Saturday afternoon and evening greatly impeded traffic, and caused much inconvenience to travellers. Sunday was dry, as was Monday, both days being cold, with the wind in the east on the latter day. Tuesday was most pleasant, for though rather cold, the sun shone brightly, and on Wednesday similar conditions prevailed.

WEATHER IN THE NORTH.—On two mornings of the past week slight frosts occurred. Generally dull and wet weather has prevailed, and little sunshine. Monday was a good day, with 3° frost in the morning and a cold N.E. wind, with threatening of rain in the afternoon.—B. D., *S. Perthshire*.

VEITCH MEMORIAL FUND.—At a meeting of the Trustees held on the 17th inst. it was resolved to place a medal and a prize of £5 at the disposal of the Trowbridge Horticultural Society, and a medal and prize of £5 at the disposal of the Borough of Hanley Floricultural Fête, to be competed for at their respective forthcoming annual shows. It was also resolved to place the sum of £20 at the disposal of the Lindley Library Trustees.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, February 28th, in the Drill Hall, James Street, Westminster, 1 to 4 P.M. A lecture on the "Colours of Insects: Their Meaning and Use" (illustrated by limelight), will be given at three o'clock by Mr. H. L. T. Blake, F.R.H.S.

THE DECOY, EASTBOURNE.—The Eastbourne Town Council has decided to purchase from Mr. Freeman Thomas a picturesquely wooded area called The Decoy, at Willingdon, for the purposes of a public park. The ground is on the north side of the borough, and comprises 82 acres. In conjunction with this purchase the Council resolved to construct a low-level drive from Eastbourne to Willingdon, with a view to its connection with the circular drive recently carried out by the Duke of Devonshire and Mr. Davies Gilbert, the local landowners.

KEW GARDENS.—A writer in a daily contemporary says:—"I would certainly recommend anyone having a spare morning or afternoon just now to take a drive down to Kew Gardens. The grounds are really looking beautiful, even at this time of year. There are thousands and thousands of Snowdrops about the place, growing in great patches under the Rhododendron bushes. The effect is very pretty, and looks for all the world as though there had been a heavy fall of snow which had partly melted, leaving huge patches of white here and there on the grass. The Crocuses are all coming into bloom, and the greenhouses are very beautiful, being filled with masses of white Lilac, Cyclamen, Violets, and other charming spring blossoms."

HORTICULTURAL CLUB.—The twenty-fourth annual dinner of the Club took place on Tuesday, 14th, at the Hotel Windsor, Victoria Street, Westminster; it was in every way a most successful one; for the first time in its history ladies had been invited and formed about one third of those present. The chair was occupied by Sir J. D. T. Llewelyn, Bt., M.P., Chairman of the Club, who, after proposing the usual loyal toasts, in happy, appreciative terms proposed the prosperity of the Club. He rejoiced greatly at the step forward which had been made, and he assured the ladies that their presence was much appreciated. This toast was responded to by the Secretary, who gave an encouraging account of the financial condition of the Club and of the harmony and good feeling that prevailed amongst its members. Mr. George Bunyard had most kindly arranged for a selection of vocal and instrumental music to be given during the evening. Mr. Harry Veitch placed a beautiful stand of the flowers of greenhouse hybrid Rhododendrons in front of the Chairman, and a sumptuous dessert, consisting of Pine Apples, Grapes, Californian Easter Beurre Pears, Peaches from the Cape of Good Hope, and Bananas, was placed upon the table owing to the kindness of Messrs. Assbee, George Moore, Peter Kay, and M. J. Garcia. The evening was a most agreeable one, and the hope was generally expressed that it would not be long before the ladies were again invited.

A GOOD EXAMPLE.—A concert was held on 14th inst. in the Village Hall, under the auspices of the Chislehurst Gardeners' Mutual Improvement Association, in aid of the Royal Gardeners' Orphan Fund. This proved a great success, as after paying all expenses the Committee will be able to hand to this deserving Institution the sum of £17 10s.

APPLE ROYAL JUBILEE.—I have a favourable word for this Apple, which I regard as one of the best in its season—November. The tree grows well, is compact and stocky, and I have no doubt when the trees are thoroughly established it will bear freely. The fact of its being late in opening its blossoms is an indication of annual cropping. The fruit is a clear lemon colour in the skin, and the quality is grand as a cooking Apple.—E. M.

SUTTON COLDFIELD GARDENERS' ASSOCIATION.—The annual dinner of this enterprising Society took place on the 14th inst. Alderman A. H. Evans (the President) occupied the chair and Councillor Vale the vice-chair. The Treasurer (Mr. C. Townshend) read a most favourable balance-sheet of the past year's management. Mr. Thos. B. Grove, the Hon. Secretary, was heartily thanked for his long co-operation, to which he responded in suitable terms. Songs and recitations contributed to the conviviality of the evening.

DOLLIS HILL.—We learn that the Willesden District Council has been considering the purchase of 98 acres of the Dollis Hill Estate, upon which they have an option. The sum asked is £50,000, a low price for such valuable land, but too large for the Council to pay; whilst the option expires at the end of April. It has been decided, therefore, to appeal to the London County Council, the Corporation, and the City Companies for help, and it is hoped in the interests of Willesden people that the appeal will not be fruitless. About 43 acres of the park are well timbered, and this part would probably be left as it is. From the high ground view can be obtained. On the east Child's Hill and Cricklewood; on the west, Neasden; on the south, Willesden Green; and on the north the ornamental waters of the Welsh Harp can be distinguished.

DEEP POTTING TOMATO PLANTS.—I may be improperly sceptical, but I have grave doubt whether the deep planting of Tomatoes, for the purpose of inducing supplementary roots to break from the stems buried in the soil is wise; or, even if wise, yet productive of better results than when the natural roots only are buried and the stems left above the soil. Really the primary object of the advocates of deep planting seems to be to enable them to hide bad culture in so raising plants from seed that they are drawn and weakly with long bare stems instead of having them leaved to the bottom, as they should be. I should like to hear of some good practical grower experimenting by planting six plants of any one variety shallow, not covering the stems as advised, and six similar plants with stems buried some 4 or 5 inches, and test results. My impression is that stem or auxiliary roots would simply act to the detriment of the natural or basal roots, and that is all.—A.

THE PYRAMIDAL PRIMULAS.—We have seen ample evidence of late of the apparent popularity of the stellata or The Lady section of Chinese Primroses, as not only now do all growers of these plants for seed have them, but they are in great demand by gardeners. All of them seed very freely. Certainly they in their original forms differ little from the inferior stocks commonly found grown fifty years ago, except that the plants have more correct pyramidal habits. Of those first introduced the flowers were poor, small, thin, and so inferior, that they were miles below the Chinese Primroses of to-day, so far as size and quality were concerned. But their charm laid in their tall, graceful, pyramidal habit of growth, making them pretty vase, basket, or room plants, and effective mixed with other plants on stages or in floor groups. But no one must rely on a popularity that is dependent on such fleeting matters as mere taste, as this, like fashion, may change every year. But if the light graceful pyramidal habit can be preserved, the flowers materially enlarged and fringed, showing greater substance, yet not too large, and giving good variety of colour, then the strain may out from general culture the very large-flowered forms that have, almost as a fault, far too large blooms, which, in falling, leave big gaps in the flower heads. No doubt some of the stocks staged at the Drill Hall the other day from Swanley have, in the direction of enlarging the flowers, gone far enough. It is evident, in relation to these, that going farther means the destruction of the pyramidal habit. One of these forms seems to be, as a greenhouse plant, perfect, and should, grown from an early sowing, easily give tall, massive heads, 18 inches over. Still, in relation to them, the possibility of picking from the plants small stems of blooms for little glasses and vases renders the plants so useful.—A. D.

METEOROLOGICAL OBSERVATIONS AT CHISWICK.

The first four days of the week were wet, and on Friday the wind changed to S.E., and brought with it fog. Saturday was also foggy, being very dense at night.

— **IN THE MARKETS.**—This is but the middle of February, yet our fruiterers are offering real Strawberries, English Asparagus, as well as English new Potatoes. The Strawberries are 10s. a basket of, perhaps, twenty-four; the Asparagus is 7s. a bunch of, perhaps, a dozen heads, and the new Potatoes are 1s. a pound.

— **SHADING GLASS HOUSES.**—Messrs. Wood & Son, the well-known sundriesmen of Wood Green, London, have sent us a sample case of the several shadings that they stock. The importance of due and proper protection of plants from too much light cannot be exaggerated, while darkness is equally injudicious. In the samples before us, and which all readers may have if they send to the makers, there are materials of every texture, from the stoutest hessian to the widest meshed hexagon netting, this latter being particularly valuable, as it is wasp-proof. The non-rotting scrim will be widely appreciated for various purposes.

— **GLADIOLUS CHILDSI.**—When Mr. Max Leichtlin, the celebrated German horticulturist, turned his attention to the finer varieties of *gandavensis*, and crossed them with the beautiful *Saundersi*, with the result that *Childsi* was produced in 1892, very few would have imagined that in this short space of time such wonderful development could have taken place. Yet so it is, and at the present time it is questionable whether we have anything to equal, and certainly nothing to supersede, them amongst the whole range of *Gladioli*. The main features of the strain seems to be the vigorous growth and long spike, the individual flowers being remarkable for size, whilst even the smaller forms seem to flower profusely. In colour every shade is represented, the mottled and spotted forms being charming. Corms purchased now, potted in 4½-inch pots and placed under glass, transferring to frame when growth commences, will be found of great use for early work and in condition for planting when the frost disappears.—R. P. R.

— **CYCLAMEN AT FARNHAM ROYAL.**—There is special pleasure in seeing Mr. W. James' fine collection of *Cyclamen* at Woodside, Farnham Royal, because, unlike the market growers, none is sent to market, and they are not unduly forced. They bloom gloriously from Christmas onwards, and when I looked into the house a few days since were in superb bloom. Then there is so much more of fire and brilliancy in the dark coloured ones, when seen under the clear pure light of the Buckinghamshire skies, and when now and then a gleam of sunshine lit up the flowers they glowed superbly. I have nowhere seen finer pure whites, whites with red and purple bases, roses with crimson bases, rich reds, and crimson reds as were to be seen here. The collection is not a great one, but it is of the finest quality; a beautiful salmon-tinted one with red base, blooming profusely, is a marked feature. None, however, excels in size, form, and floriferousness the pure whites, dark base whites, and roses and the blood reds. Some of these latter have flowers quite up to the form and dimensions of the giganteums, for the giant form dominates all the strain. There are a few of the new and oddly formed *Papilio* strain, but the plants are not strong; even the best, however, show blooms that look poor as compared with the noble, erect, and finely formed flowers of the older stocks. The prettiest is a red that has flowers of ordinary *Cyclamen* form, the edges of the petals being slightly fringed.—WANDERER.

— **DWARF KIDNEY BEANS.**—Very interesting should be the trial of these summer Beans, which is to be carried out on an extensive scale at Chiswick this year. It is intended to sow all varieties having seeds of similar appearance side by side, as that will enable comparisons to be more readily made. No doubt comparatively thin sowings will also be practised, as it is only when ample room is given that plants can display their true characteristics. There seem to have been many additions to our list of Dwarf Kidney Beans made during the past few years. All the same, because of the nature of the plant, no very striking variations can well be furnished; but of the newer ones, some may be found fit to supersede old varieties. Obviously the short-podded forcing section will make a poor show outdoors compared with some others, but their uses for forcing cannot be too highly estimated.—D.

— **AMERICAN FRUIT GROWERS.**—The fruit growers of the United States (chiefly those of the Pacific slope) supply at least four-fifths of all the green fruit consumed in Manitoba and the North-west Territory of Canada; but there is a likelihood, owing to the energy of our Canadian cousins, that this practical monopoly of the market may not be maintained in the future. Owing to the excellence of their product and the great care they have exercised in its selection and packing for shipment, the States fruit farmers have been able heretofore to defy the competition of Canadian producers, notwithstanding the fact that the latter have much the advantage in shorter lines of transportation. Now Canadians seem to be waking up to the situation, and are bringing urgent pressure to bear upon the Dominion and provincial boards of agriculture to induce them to assist in providing better facilities for preserving, packing, and transporting Canadian fruits. These bodies have hitherto, says the "Rural World," bent all their energies toward securing our own and other European markets, but are now making a vigorous effort to capture the home trade. Encouragement is being given to the erection of cold-storage plants and packing houses, and transportation lines are being worked. The United States system of packing fruits has been adopted, and altogether a much stronger bid will be made for these markets than previously.

— **FEVER IN PLANTS.**—Some experiments by Mr. H. M. Richards are thus epitomised in a note in "Natural Science":—"He finds that accompanying the increased rate of respiration is an increase in the temperature of the parts affected. A kind of fever supervenes, and, as in the case of respiration, the disturbance runs a definite course, and attains its maximum some twenty-four hours after injury. It is interesting to note that the attempt to rally from an injury is accompanied by somewhat the same symptoms, increased rate of respiration, and evolution of heat in plants as in animals. Owing to the nature of the case, the reaction is less obvious in the former than in the latter, and a delicate thermo-electric element was required to appreciate the rise in temperature; but, compared with the ordinary temperature of plants in relation to the surrounding medium, the rise after injury is 'as great, if no greater, than that in animals.' The maximum in all the plants investigated was between two or three times the ordinary excess above the surrounding air. Potatoes proved the most satisfactory objects for experiment, and it was found that in massive tissues (such as Potatoes or Radishes afford) the effect of injury, was local, whereas in the case of leaves (e.g., Onion bulbs) much greater extent of tissue was sympathetically affected."

— **ROYAL METEOROLOGICAL SOCIETY.**—The monthly meeting of this Society was held on Wednesday evening the 15th inst. at the Institution of Civil Engineers; Mr. F. C. Bayard, LL.M., President, in the chair. Mr. E. Mawley, F.R.H.S., read his annual report on the phenological observations, and stated that the weather of the past year, taken as a whole, had been throughout the British Isles very warm and dry. Wild plants blossomed much in advance of their average dates until about the end of March, but after that time until the close of the flowering season they were mostly late. Favoured by the rains in May the crop of hay was everywhere a remarkably heavy one, but the long drought which followed dried the pastures, and caused a scanty yield of roots. The dry season suited the cereals admirably, and especially the Wheat, of which there was a very abundant crop. The yield of Barley was nearly as exceptional, while that of Oats, except in the north-east of England and in Scotland, was also unusually good. There was a splendid crop of Potatoes in Ireland and in parts of Scotland, but elsewhere the yield was, on the whole, moderate. Apples, Pears, and Plums flowered abundantly, but adverse weather conditions, and the dry subsoil in the spring, caused an irregular "set" of fruit, so that in all parts of the kingdom these crops were, as a rule, below average. On the other hand, there were good crops of all the smaller fruits. A paper by Professor W. M. Davis of Harvard University, U.S., on "The Circulation of the Atmosphere," was read by the Secretary.

— BIRMINGHAM GARDENERS' ASSOCIATION.—At the recent tea and social gathering of this Society, held to celebrate the thirteenth anniversary, the newly appointed President, Prof. Wm. Hillhouse, occupied the chair, with Mr. W. B. Latham as Vice-Chairman. The Professor expressed the pleasure it afforded him in being elected as President of the Association, of which he had had the honour of being the Vice-President ever since its inception. He gave an interesting review of the work of the Society, and commented with satisfaction upon its programme for the ensuing year, and especially upon the proposed visit to Woburn Abbey, the historic seat of the Duke of Bedford, famous for its arboreal features, and to the Duke's experimental fruit farm. The enjoyment of the evening was much enhanced by the instrumental and vocal renderings of several of the members and lady friends.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 14TH.

SCIENTIFIC COMMITTEE.—Present: Mr. McLachlan (in the chair); Mr. Hudson, Rev. W. Wilks, Mr. Michael, and Rev. G. Henslow, Hon. Sec.

Diseased Apple twigs.—These were received last December from Rev. A. Foster-Melliar. Prof. W. E. Smith, after a prolonged and difficult investigation, has pronounced the disease to be due to bacteria, and forwarded the following interesting report:—"The portions of branches of Apple sent show a disease with the following characters. The wood is sound except where in contact with the bark; the bark is completely disorganised with exception of the hard fibres and the dry outer corky layer. Investigations for signs of fungi or insects made on arrival of the material (December 19th) gave no result. Portions were placed in a moist chamber and examined during January. The bark became soft and spongy, no fungus-growth appeared, but bacteria were found in numbers. Amongst other bacterial forms, a bacillus was common which agreed with that figured by Duggar (Cornell University Bulletin, 145, 1898). Other symptoms, as far as presented by the material sent, agreed with American descriptions of the bacterial disease 'fire-blight.' We have, however, no record of the tree having blackened twigs or leaves during last summer—an important symptom of this disease. 'Fire-blight' was proved, chiefly by the work of Burrill in 1880, to be due to the action of bacteria. A good general account, based on further research, is given by Waite (Year Book of the U.S. America Department of Agriculture, 1895). The disease appears in America on Pear and Quince oftener than on Apple, and is also known on allied species. It attacks chiefly vigorous well fed trees with much soft young wood, similar, in fact, to this Apple tree as described by your correspondent. A warm moist season or situation favours the disease; dry weather checks it, and during winter it makes little progress. The remedy is to prune off thoroughly all parts which show discoloured or destroyed bark, and to carefully burn them. Pruning is best done in autumn or spring. The cuts must be made well below diseased parts, and large wounds should be painted with tar. If the pruning be severe it may induce a large growth of young wood next season; this must be carefully watched, as it is an excellent starting point for a reappearance of the disease. The bacteria are propagated by insects, which visit a gummy fluid containing bacteria which is given out from diseased parts of the bark. Then they visit a similar fluid exuded from the bark where broken by cuts, boring insects, or other agents, and they infect this with bacteria. A similar fluid in the flowers also tempts insects there, and the bacteria thus introduced destroy the fruit crop." A unanimous vote of thanks was given to Prof. Smith for this valuable report.

Tupistra nutans.—Mr. Jas. Hudson exhibited a specimen of this uncommon plant in blossom. There are but four genera of the *Aspidistrea*, a tribe of Liliaceæ; *Tupistra*, with 304 species, being natives of Himalaya or Burmah. It bore dense spikes of white flowers with an expanded border and a dark centre.

Pear tree with caterpillar.—Mr. McLachlan showed a twig with the interior eaten away by the caterpillar of the wood leopard moth, *Zeuzera Aesculi*. It was received from Mr. N. Nutter of Leigham Cottage, St. Julien, Old Streatham. The best remedies for this and boring beetles is to run a stout wire down till it pierces the grubs. Petroleum or spirits of turpentine poured down the hole would also probably be effective in destroying them.

Richardia, two-spined.—Rev. H. F. Goffe, Thoresway, Caistor, forwarded a specimen in which the uppermost leaf had assumed the form of an additional spathe—a not uncommon phenomenon. It was hoped that experiments would be made to fix this peculiarity if possible.

Cedar with aerial roots.—The following communication was received from Mr. J. W. Odell, The Grove, Stanmore, together with photos of the tree described, and a large mass of aerial roots:—"During the recent heavy gales considerable damage was done to one of the large Cedars of Lebanon in Mrs. Brightwen's grounds here; a huge branch was torn from the parent trunk, and revealed a very curious growth of aerial roots. I forward to you with this letter photos showing the broken branch in two positions, and also a part of the very large growth of adventitious roots. You will observe on photo (marked A) a large scar, corresponding in size and shape to the base of the branch on photo marked B. The roots sent

were growing from the edges of the contiguous portions of the trunk and broken branch, and grew downwards from this position towards the base of the tree, but had only penetrated so far as is indicated by a small branch at the base of the scar (seen on both photos). Both on the branch and on the scar left on the trunk the wood is very much splintered, and the roots were found not only in a large mass as sent, but also growing in between the splintered portions of the wood. The appearance of the fracture indicates, I think, some previous injury (perhaps by lightning), and as a consequence some moisture may have penetrated into the union between the trunk and the branch. I have once or twice before seen similar roots in broken pollarded Willows, but have never observed the formation of such adventitious roots in a Conifer, and thought perhaps it would have some little interest for your Committee of the R.H.S."

R.H.S. MEDALS.

WE seem destined never to hear the last of these Drill Hall awards. The Council in the recent report again adverts to them, and suggests that in making awards the Committees should remember more fully the distinctions that exist between traders' and amateurs' collections. In a certain sense the Committees will no doubt go on sinning, but the last thing needful is the drawing the various Committees' attention to the diverse positions of trade exhibits and those of amateurs, because the exhibits do that so thoroughly themselves. Take the recent meeting, what amateur could at this time of year put up a collection of Apples that could for one moment approach the grand collection Mr. Bunyard sent? Really not in all the world could anything like so fine a stand be seen elsewhere. There was the superb collection of Camellias from Mr. W. Paul, the beautiful Ferns from Mr. H. B. May, the beautiful Chinese Primroses from Messrs. Veitch and H. Cannell, just to indicate a few as samples of trade exhibits in comparison with which amateurs have nothing approaching them to show.

How is it possible for any just body of men in making awards to overlook the splendid evidences of culture seen? What is it to me who is the exhibitor? It does not concern me, or probably any other member of a Committee, who the exhibitor may be. The awards I vote for are made to the culture and the quality, and sometimes the rarity of the exhibit, as was the case with the wonderfully fine exhibit of Vanilla from Syon. The general public would never understand reasons why all amateurs' inferior products were put on the same plane of merit as superb trade ones.

There seems to be no midway between the present and not illiberal, yet not unduly liberal, method of granting medal awards, or of refraining from granting any whatever, not that I think anyone cares much for the real medal, so long as they get the card one, and the award is seen and recorded. Certainly much expense might be saved, and far more satisfactory results to exhibitors insured, if only card awards were made, each such award counting so many marks, and then at the close of the year some handsome medals worth having, or fancy plate, or other useful objects were given to the various exhibitors, in proportion to the number of marks obtained during the year.

The President of the Society mentioned that realising the granting from time to time of gold medals ostensibly, and not in reality, was an impropriety, a small die had been obtained to enable small gold medals, when awarded, to be given in future.

Mr. Elwes thinks the gardeners who really produce the exhibits at the Drill Hall should have medals awarded them, but seeing that by far the greater portion of the exhibits come from the trade, that proposal will hardly be found workable. There is not a gardener in the kingdom but would prefer medals with the Queen's profile on them to any of the Society's. If the getting of medals is the chief aim of exhibitors in sending such wonderful collections of exhibits to the Drill Hall, as between giving the medals or losing the shows, let the giving go on by all means.—A. D.

ASPARAGUS "MADE IN GERMANY."

MUCH has been written in the Journal lately about Asparagus, and I think it might interest some readers, although of no particular practical value, to know how they grow the "Grass" in Germany. Here, in Erfurt, there are considerable plantations, and it seems to do very well. The soil is a rather heavy but well drained loam, and as there is a salina in the neighbourhood, good grey salt can be obtained at a moderate price.

The treatment is different from ours, as only blanched stems are eaten, and if the tip has more than the slightest tinge of purple about it, it does not sell. In the plantation with which I am best acquainted, the crowns are covered with about 1 foot of earth the second year after planting, and are arranged in beds of two rows 18 inches apart with alleys between. When vacancies occur through plants dying, a hole about a foot across is dug, and the young plants placed in the bottom; the second year they are earthed and marked with a stake to show that they are not yet ready for cutting. In November the old stems are cut down, a dressing of short manure is spread on the surface, and the whole place dug over. In the height of the season the cutting begins at four in the morning and continues till sunset. As soon as the shoots cause the surface to crack a hole is scratched, and they are cut off with long knives made for the purpose.

From this it will be seen that it is laborious work on a large place. If the year is good, fine Asparagus may be had in the shops from 6d. to 9d. per lb. in the height of the season, but as labour is cheap the growers still secure a very good profit. I suppose it is a matter of fashion and custom, but I must say I find the green English Asparagus has more flavour.—C. S. H.

TROPICAL GROWTHS IN CEYLON.

PROBABLY few countries of the same size possess within so limited an area such numerous and diversified products. Taking that delightful vapour bath Colombo as a base from which to explore, one finds, of course, trees that delight in an equable steaming shade temperature of some 80° to 90°, and which may reckon upon, in addition to the ozone from the ocean, a more or less diurnal dose of rain. Here, then, the Banaua, Cocoa-nut, Mango, Bread-fruit Tree, with great varieties of Palms and Bamboo, flourish in common with spices innumerable. Pine Apples, Oranges, Pomegranate, and such like.

I suppose people get callous to it, but certainly I did feel qualms in letting the poor Cingalese coolie run for miles in this sweltering climate with his whole body, shining as if anointed with oil, steaming with perspiration. At Singapore it is, of course, just the same. They seem so wonderfully willing, however, and run mile after mile without seeming to expect to stop (luckily, Colombo itself is extremely flat), that one gives up the problem, unwittingly absorbed, it may be, by the objects of interest all around. One very long rickshaw run I took, right away round the lake to the Cinnamon gardens, and by a circuitous route back to the further end of the long sea front promenade. The fellow scarcely slowed to a walk more than once or twice. No one seems to attempt to walk in this place—perhaps after a year or two people are so enervated that they cannot; but as a passer-by, and at all times a keen advocate of shanks' mare, with the vitality of good Old England within me, I not only walked frequently, but sometimes even a considerable distance, and once indulged in the additional exercise of butterflying, and that, too, in the chief heat of the day. Curiously enough, I seemed to find little difference whether I lay under my mosquito curtains *in puris naturalibus*, or inclined any person in a long open chair on the verandah, or allowed my lordly limbs to be rapidly impelled through the air by a son of the soil, or whether I took the said pedestrian exercise *in propria persona*; in whatever case the result was the same—viz., I seemed covered with a perspiration oozing out of every pore from head to foot. Of course, up at Kandy it is not so bad. Here you may walk along lanes absolutely embowered in leafy foliage and overhanging fruits of multitudinous design, shape, and colour.

I know of few more beautiful spots than this lovely place, with its alluring lake and fascinating surroundings, not the least interesting, apart from the wonderful and varied growths all around, being the picturesque and very ancient Buddhist temple, the old librarian of which handed me his Cingalese carte-de-visite on making our adieux. Truly did I find Kandy and its vicinity a veritable Paradise. I think any month there was February, and though the insect creation was not yet in full swing, I obtained quite a tolerable amount of gorgeous butterflies wherever I directed my footsteps. The most curious, and one I believe to be found nowhere else, was a blue one with a single long horn or snout, half beetle and half moth, extremely pretty when fully extended. This I found on one particular tree in the Peradeniyeh Gardens. These most lovely grounds were my happy hunting grounds *par excellence*. A little Cingalese lad used to meet me there and do the running about, thereby helping me make quite double my usual "bag."

The flying fox which swarms in a large rookery here is a most curious creature. Neither shall I forget the exactions of a charming American lady (following her husband, a naval captain, round the world), whose interest centred to an extraordinary degree in the numerous species of Palm (no small order in itself), and tropical trees for which these gardens are famous. Among the former I think the Sealingwax Palm most appealed to me, the stem of which looked indeed like nothing else than a colossal piece of red sealingwax. Several plants we grubbed up together, but, alas! like some ravishing white Orchids which I slipped from the trees at Singapore, so far as I am concerned, none survived.

Walking back in the comparative cool of the evening from Peradeniyeh to Kandy, one passes under a canopy of branches from each side the road of Banana, Cinnamon, Nutmeg, Mango, Vanilla and Bread-fruit trees, to say nothing of numbers of flowering shrubs, scarcely noticing here and there tiny huts of Bamboo and Palm, so hidden are they among the foliage. A good deal of hillside in this neighbourhood is cultivated with Cocoa, Tea, and Coffee plantations. We saw, too, something of Sir Thomas Lipton's vast grounds.

Perhaps the most exquisite delight which I experienced while at Kandy was the nocturnal rickshaw ride. Sauntering along and dreaming of many things in the cool of the evening, after a generous dinner, a Cingalese runner would insidiously suggest to you, in a whisper, gliding out from the darkness, the delights of a run. It invariably ended in my finding myself sitting back in a rickshaw, feeling as if I had not a care in the world, smoothly and noiselessly gliding along up hill and down dale, miles away, with the weird moonlight flitting across the paths and playing among the thick leafy glades on either side. I think I have never experienced anything so soothing, or a temperature more ideally perfect

than these impromptu rides in this beautiful spot of Ceylon's spice-laden isle.—T. A. CARNEGIE-CHEALES.

DISBUDDING VINES.

To the Grape grower who, in addition to being a good practical gardener, has also the necessary amount of enthusiasm to make his work enjoyable, the closing days of winter are interesting times. The rain may come down in a deluge, and the wind roar and whirl in fitful fury; what matters, these will only have sway for a time; spring is at hand, when old Sol begins to assert his power and awaken all Nature into active life. The Grape grower is, perhaps, the first to note and welcome the signs of spring, for the lengthening days and pleasant spells of sunshine act like magic upon early forced Vines, tending as they do to promote rapid growth, as well as to give substance and colour to the leaves.

The buds in successional houses will now be breaking fast where a little fire heat is employed to forward them, and ere long Vines in late houses will also be bursting into leaf. Disbudding, stopping, and tying will therefore be the order of the day for some months hence, and although the work is simple enough, it is quite easy to make errors in carrying it out. A mistake often made is to treat all Vines alike in the matter of disbudding, without paying due regard to the style of pruning adopted or the type of shoots produced. Let us therefore consider the treatment best suited for Vines of various descriptions.

Young Vines which are not required to produce large bunches of Grapes are usually pruned to one bud, and a good practice it is, because compact bunches are thus secured. In this case there is, of course, little choice in the matter of shoots, as each spur produces one strong one, and generally a few weak ones around it; the latter should be rubbed off as soon as they begin to burst. In cases where the Vines are pruned to two eyes the two best shoots ought to be retained for a time, as it often happens that the shoot at the extremity of the spur produces several joints before the bunch shows, while the shoot from the basal bud sends out its bunch quite near the rod. This is usually the better one to retain, unless a large bunch is required, but generally speaking the bunches which show at some distance from the main rod are loose in the shoulders and long in the footstalk, characteristics not valued by good Grape growers.

As soon as the character of each bunch can be discerned the selection ought to be made and the superfluous ones removed. Young Vines which made their rods last season must be carefully disbudded, as upon the selection now made will depend the ultimate positions of the spurs. The buds retained should be as evenly placed as possible from 15 to 18 inches apart on each side of the rod, so that a shoot on one side is disposed midway between two on the other. It is not always easy to secure growths at just the right point, but the nearer the plan is adhered to the better, even though in a few instances a comparatively weak shoot has to be retained in preference to a stronger, but misplaced one.

Now let us deal with Vines pruned on the long-spur system—i.e., leaving the growths from 6 inches to a foot or more in length, we thus get plenty of good shoots to select from. The one carrying the best and most shapely bunch should be here retained, no matter where it is situated; but—and this is important—a shoot must also be retained at the base of the spur. The latter, if stopped at four or five leaves will form a moderately strong growth, and at pruning time the following year some of the spurs can be cut back to such shoots. With this treatment large bunches of Grapes are obtained, and long spurs may at any time be removed. The principle is in reality exactly the same as that adopted in the disbudding and pruning of Peach trees. Muscats, Gros Guillaume, and Madresfield Court are varieties which succeed well under this system.

The advantage of having plenty of young wood on old Vines at pruning time has many times been advocated in the *Journal of Horticulture*, but hand in hand with that practice must go judicious disbudding if the Vines are to derive the fullest benefit. In such instances it is not advisable to do the whole of the disbudding at one time; a little extra growth for a time will help to increase root action, and put new vigour into feeble veterans. Only the weak buds must be removed at first, allowing the other shoots to remain till they are 3 or 4 inches in length; the most promising can then be selected, and the others removed by degrees, always retaining a growth near the base of the spur whenever opportunity occurs.

Overcrowding should of course at all times be avoided, but it is well to bear in mind that very old Vines do not often produce strong shoots, and enough ought to be left to completely cover the available space, as every leaf of good texture means increase of force in the Vine. When it is intended to take up young rods a sharp look out must be kept at disbudding time for well placed shoots at the front of the house. It is an easy matter to overlook this till the growths are tied down, then it is found that just the one required has been removed.—H. D.

THE SHERWOOD CUP.

IT having been represented to the Council of the Royal Horticultural Society that the terms in which the Sherwood cup is offered for competition on page 52 of the Society's Arrangements for 1899 are not sufficiently definite, the following additional regulations are made:—

1. No exhibitor may stage more than 100 dishes in all.
2. The 100 (or less) dishes may be divided between the two meetings in any proportion the exhibitor pleases.
3. Special regard will be given to quality and to variety.
4. As with all other exhibits for prizes, all the exhibits must have been actually grown by the exhibitor in his own or his employer's garden.—W. WILKS, *Secretary*.

By order of Council, February 14th, 1899.

WINTER PRUNING.

A NOVEL COMPETITION.

SOME fifteen or more years ago, the late Earl Beauchamp, with a view to the encouragement of the hardy fruit growing industry on the estate and the improvement of the property, decided to set apart a few acres of land for the raising in quantity of hardy fruit trees. These were proved to be the most suitable for the locality, and then distributed gratuitously to his tenantry, both small and great. The number of trees thus disposed of varied from 1000 to 2000 trees per annum.

It will thus be understood that this increased area of young orcharding meant some attention in the shape of pruning. Here began the difficulty, for outside the garden proper a workman sufficiently skilled could not be found; and as for the conceited jobbing gardener, his services were obviously worse, if judged by the work one sees him do in suburban gardens. It will thus be seen that the art of pruning in our rural districts is nearly defunct, and, as a matter of fact, our old orchards are living demonstrations of the truth of this.

In order to improve this state of things with other similar deficiencies, a club or society was formed some half-dozen years ago, having for its object the encouragement and improvement of labour in our rural districts by spreading technical instruction from various experts. The Club was fortunate in obtaining the services of the present Lord Beauchamp for its president—a nobleman who occupies a seat as a Progressive member of the London School Board, and who takes the deepest interest in technical education of all kinds, and who was consequently able to bring considerable tact and experience to bear upon the organisation at every opportunity. At first the Club's funds only were available for providing a series of lectures and demonstrations, held in the orchards by myself, but of late years the County Council have made grants in assistance thereof.

Amongst other competitions of this year a pruning exhibition was arranged, and which, if taken as a test value of the instruction, has certainly proved a signal success, and extremely encouraging towards the continuance of the experiment. The competition took place on February 16th in a 10 acre orchard of young flourishing trees about ten years planted. The farm having been in hand the trees had hitherto received fair attention. Two classes were arranged. Class A for farm hands only, and class B open for all; 20s., 10s., 5s. were offered in each class. The conditions ran:—To the person who shall prune with knife, saw, chisel, or other suitable tool, in not more than three hours, four young trees in the best manner; time also will be considered. Unsuccessful competitors to receive 1s. each.

The trees were previously selected as nearly equal in all respects as possible by an appointed steward; two Apple and two Pear trees for each competitor, with numbered cards attached in consecutive order. Corresponding cards were prepared and kept for balloting purposes.

Sixteen competitors answered the roll call. The ballot took place, each competitor drawing a card from the steward's hands, which identified his list of trees. At a given signal the work commenced, and as soon as each competitor finished he returned his number to the steward, who was stationed ready to receive it and register the time; the card, with the time stated on, being afterwards handed to the Judges for point value. The Judges—Messrs. Coleman of Eastnor, and Waid of Stoke Edith—carefully watched the progress of the work, and summed up the points at the competition.

Various styles were adopted, and the old primitive chisel was used in one case. The general character of the work was above average merit, and extra prizes were awarded in each class. Some of the competitors were in too great a hurry to make neat skilful work, while others failed to smooth saw cuts. One of the most gratifying features was that nearly all the prizes were awarded to comparatively

young men, who had followed closely to the instructions given at the demonstrations and lectures.

The event created the greatest interest and enthusiasm within the radius of the Club, and a goodly number of anxious spectators watched the proceedings throughout, and patiently waited to hear the results. After so successful an experiment doubtless the competition will be repeated and extended.—W. CRUMP, *Madresfield*.

THE BEST PEACHES.

BY way of response to "H. D." (page 119), in reference to the conditions most favourable to the successful cultivation of that exquisite Peach Noblesse, I beg to say that, in my own practice, I was never able to produce it in such perfection as at Archerfield, in East Lothian. The soil and water at that place were so strongly impregnated with lime that neither Camellias, Heaths, Rhododendrons, nor other hairy rooted plants would live in it. The Camellia, of course, is not a hairy rooted plant, but it did no good under the lime influence.

The Peaches did remarkably well, and especially Noblesse, and seemed to be in a most congenial element. It bore freely, and brought to maturity much finer fruit than I have ever seen it produce in any other district. Perhaps these remarks will come under the eye of someone who may remember the collection of fruit I put up for "The Gardeners' Chronicle" prize at the Great International Fruit Show in Edinburgh in 1865, in which collection there was a dish of this Peach that one of your contemporaries described as absolutely perfect.

The soil of the place referred to produces all Peaches in very fine form, and Noblesse in particular. This leads to the suggestion that it is questionable if Peaches in general get as much lime as is good for them.

With regard to the varieties "H. D." recommends little or no fault can be found. Violette Hâtive and Bellegarde are two old varieties that may be said to be almost faultless, and the same may be said of Royal George where it is not given to mildew. Where it is any trouble in this respect Dymond is a splendid substitute. Even where Royal George succeeds Dymond is worthy of a place. It is equal in cropping freely, of fine flavour, and larger.

Alexandra Noblesse is a grand second early Peach producing large handsome Noblesse-like fruits of good quality. It is rather a shy bearer when in a late cool house, and is inclined to grow strongly, calling for periodical lifting.

Raymaekers is also a fine second early variety producing very large fruits, in other respects having a strong resemblance to Noblesse, but considerably larger.

I can endorse all "H. D." says of Sea Eagle as a late variety. It is a most fertile variety, and one of the few that can be kept in the fruit room in good condition. This and the old Walburton Admirable are two fine late varieties; the latter, however, is not so free as Sea Eagle.—D. THOMSON.

PHYSIANTHUS ALBENS.

THE white Bladder-Bloom is a member of the *Asclepias* family, and was first described by Van Martius in his work on Brazilian plants, from specimens which that botanist collected in the woods of Ypanema in the province of St. Paul's. Seeds were sent to this country in 1830 by Mr. Tweedie of Buenos Ayres, and the plants produced flowered freely in 1831, from which an illustration was prepared for the "Botanical Magazine" (t. 3201, 1832). A few years after examples of the same plant were sent to Mr. Lindley, then Editor of the "Botanical Register," with the statement that they had been received from Mexico apparently in mistake, as was explained when the flowers were figured in the work named (t. 1759, 1836). In Decandolle's "Prodromus," vol. viii., page 533, this *Physianthus* is referred to the genus *Arauja*, which has been adopted by several authors since, with it being associated *A. sericea* (formerly known as *Apocynum Peruvianum*), *A. calycina*, and *A. angustifolia*, all natives of Brazil or neighbouring districts.

In cultivation the *Physianthus* has always been scarce, being confined to botanic gardens or a few private gardens where curiosities are prized. This is probably due to the fact that it cannot claim a prominent place on account of its beauty, though the white flowers possess a powerful fragrance, and when the plant is bearing its large twin fruits (fig. 30) it is very remarkable. Like many of its relatives it is of twining habit, producing the white flowers in small stalked clusters (usually four each) from near the axils of the opposite bright green leaves. Before the corollas expand they have a curious inflated appearance, and to this it owes the generic name, popularly rendered "Bladder-Bloom." The fruits are rarely

produced under cultivation, and in the figures we have cited, which are the only ones known to us, this most characteristic feature is omitted from the absence of materials. When mature the fruit measures about

is then very ornamental. It is probable that by artificial fertilisation these fruits could be more frequently obtained on cultivated plants, but, as with other *Asclepiads*, the method of fertilisation is strangely different

FIG. 31.—THE WHITE BLADDER-BLOOM, *PHYSIANTHUS ALBENS*.

8 inches from tip to tip of the two lobes, but occasionally only one of these is produced or becomes fully developed. The surface is curiously wrinkled or puckered, and when ripe it assumes a rich orange colour, and

from most plants, and a good idea of the arrangement of the organs can be obtained from a careful examination of one of our common hardy *Asclepias*.

THE HISTORY OF THE ROSE.

At the last fortnightly meeting of the Devon and Exeter Gardeners' Association, an instructive paper, prepared by Mr. E. J. Love, of the Mount Radford Nurseries, was read, entitled "The History of the Rose." The earliest records of cultivation of the "Queen of Flowers" took them, he said, back to the days of ancient Greece and Rome. Theory justified them in assuming that the Rose came from the central or western central part of Asia. That the Greeks used the Rose for personal embellishment there could be little doubt; they were lavish in its use at their public festivities and religious ceremonies, not only dedicating it to their gods and goddesses, but investing it with many supposed medicinal virtues.

During the days of the Roman Empire the Rose occupied a high position, and many districts became famous for their Rose gardens. Of the colour of their Roses they only knew red and white. So far as substance of petal and solidity of bloom were concerned they could only conjecture; but they must have attained a much higher state of perfection than would have been imagined so long ago. From the fourth to the sixteenth century scarcely anything was known of the Rose as a cultivated plant.

The coming of the Rose into England took place about the beginning of the sixteenth century. In 1629 they were told that there were twenty-four varieties, in 1730 forty-three, and in 1770 seventy-nine. The Moss Rose was introduced from Holland in 1596, the Austrian Briar came the same year, the Rosa multiflora in 1801, the China Rose in 1789, and from the Celestial Empire in 1810 came the first Tea Roses. Looking back over a period of 2000 years, he ventured to say that never before, not even in Rome's palmy days or in the zenith of Grecian glory, had the Queen of Flowers such devoted and loyal subjects as to-day.

Lord Penzance's charming Sweet Briar was the most notable addition to their Rose gardens of late years, but he was afraid that although a "thing of beauty" it would not be a "joy for ever." He thought it was a trait in their national character that beauty alone did not permanently attract them. He looked more to the Tea and Hybrid Perpetual section to maintain the high position attained by the "Queen of Flowers."

Mr. W. Mackay occupied the chair. Owing to the very bad weather the attendance was small. A vote of thanks to the lecturer and the Chairman was passed after a rather interesting discussion.—"Devon and Exeter Gazette."

DECORATING FRUIT EXHIBITS.

MR. JEFFERY, on page 82, suggests as a defining line between collections of fruit the introduction of epergnes and vases of flowers, which he thinks would convey a striking decorative effect to the fruit tables. If it were practicable to afford the space needed to the flower and fruit exhibition separately for staging no doubt the imaginative picture drawn by your correspondent would be an effective one. In actual practice, however, there would arise some friction between the two sections, because, unless special facilities were provided, one would get very much in the way of and prove a hindrance to the other. Those who have had a long course of experience at exhibitions will readily admit this difficulty, while it may be just as truly said the idea of placing the floral decoration exhibits between those from fruit growers would make a novel and very pretty blend.

The two objects, however, are widely separated, and as a rule the owner of the one has not a prominent sympathy with the other, and this, I feel certain, would not be mutually strengthened by bringing the two in conflict one with the other. The grower who had fine Grapes to stage would feel nervous in having so close an association with the epergne dresser, and *vice versa*. The only satisfactory method of dealing with the suggestion is for societies to find separate tables for the florists' use, with the spaces so arranged that they can stand the vases in their places after the fruit is staged, and the solution of such a difficulty is easier of imagination than is the actual carrying out of the work in the show tent. There are few flower shows where the officials do not find a difficulty in dealing with entries on the morning of the show, and these would be still further added to if the limit of time allowed were hindered by the introduction of epergnes and vases.

I quite agree with Mr. Jeffery, as will many other readers and exhibitors, that much confusion exists in the arrangement of the fruit collections at some shows, and often without any real necessity. It is not unusual to see these classes huddled together at one end of the fruit tables, and the other end scantily filled, from no other reason than that no estimation of space is made relative to the number of entries. Unlike Chrysanthemum shows, there are no rules as to the size of the Grape stands, which usually govern the extent of space required for fruit

collections, and it is this uncertainty alone in regard to space required that invariably accounts for the crowding and confusion that exist, when each exhibitor is given an equally measured space.

A collection of fruit is usually looked upon as the most important class, but due regard is not always paid to its position and arrangement; the matter of a few inches in the space required is frequently made a cause for unnecessary friction. The difficulty of defining between exhibits could be easily decided by having wide strips of coloured materials left unfastened until the space for each collection is determined, and if each exhibitor was expected to furnish the amount of space required for the Grape stands, officials would then be in possession of the necessary information for measuring the spaces. This is solicited by some societies in their schedule, but I have never heard of a case where disqualification followed the non-observance of the rule. If such materials were provided as that suggested, and instructions given to exhibitors on the show day to the effect that they were intended as a dividing line, it would be very simple for the definition to be clearly proved, for the information equally of judges, exhibitors, and the patrons of the society.

Personally, I believe it would be better to allow the decorative aspects of the fruit tables to remain in the hands of those who stage them, no great effort, or large quantity of material is required to give a pretty turnish to collections of fruit. It must be admitted that occasions are not so frequent as they might be where effective decoration is applied to fruit collections, and which I think lend themselves very readily to such treatment. Some fruit growers consider decorations beyond leaves for plates absolutely superfluous. This, however, is strictly a matter of opinion, and will always remain so between adherents of the practice and those who look upon it with disfavour. Trails of green or coloured Virginian Creeper of the small-leaved kinds, Smilax, Lygodium scandens, fronds of Lycopodiums or Maidenhair Ferns, can all be adapted to the purpose. W. S., Road Ashton, Wilts.

COVENT GARDEN MARKET.

TOWN *versus* COUNTRY GROWERS.

LITIGATION has arisen between a number of market gardeners growing fruit, flowers, vegetables, roots and herbs in the neighbourhood of London, for sale in Covent Garden Market, and the lord of the market, the Duke of Bedford. His Grace owns the market under letters patent granted by Charles II. A private Act of Parliament was passed in 1828, regulating the market and fixing tolls to be charged to "growers" frequenting it and occupying the stands with their waggons or carts for the purpose of selling their goods. The plaintiffs have brought their action for the purpose of claiming a declaration that they have statutory preferential right to hire three classes of stands—viz., the casual cart stands, yearly cart stands, and yearly pitching stands. They allege that the duke had been excluding them, and refusing them these stands, even when vacant, or filling the stands with other than growers so as to prevent growers having the use of them, with the result that the plaintiffs have had to go to other stands or to places outside the market, where the conditions imposed by the Act do not apply, and higher tolls are exacted.

To all this the Duke of Bedford replies with the contention that the stands were intended to be available for growers throughout the country, and that this action is a scheme by which the growers round London who cart their produce to market seek to get possession of the thirty-eight casual cart-stands, so as to exclude all the growers who send their goods up by train. The case has not yet reached the trial of these interesting issues, in which the public have concern as well as the growers and the ducal owner. At present the action has reached only a preliminary stage—viz., the legal right of the six plaintiffs (who are market gardeners) to join together in bringing one representative action on behalf of the whole class of growers. The duke raised this point by taking out a summons to have all proceedings in the action stayed on the ground that the plaintiffs having separate and distinct causes of action could not, as private individuals, sue on behalf of a class of the public in respect of public or statutory rights. Mr. Justice Romer decided in the duke's favour, and plaintiffs appealed.

The Master of the Rolls and Lords Justices Rigby and Vaughan Williams delivered judgments on the appeal on Tuesday. The Master of the Rolls said that if he could come to the conclusion that the action was frivolous and that the growers had not any rights at all either against the public or against the Lord of the market, it would follow that the action was in his opinion misconceived; but he could not come to the conclusion that there was nothing honestly to try in the controversy. When the Market Act was passed London was supplied with fruit and vegetables by the market gardeners round about; but now growers sent their produce from Cornwall, Scotland, Ireland, and even from California; and as to what "growers" as referred to in the Act now meant he said nothing. But he found that "growers" had certain statutory rights, and the right which the plaintiffs claimed was a statutory preferential right over three classes of stands. If, as they said, all their preferential rights were ignored, he could not see why that question could not be raised in one action instead of three. In his view, therefore, the appeal must be allowed. Lord Justice Rigby was also of opinion that the case was a proper one for a representative action by one or more growers. Lord Justice Vaughan Williams arrived at a different conclusion. He thought that the judgment of Mr. Justice Romer was perfectly right.

In accordance with the judgment of the majority of the Court, the appeal was allowed and the order of the Court below discharged, upon the undertaking of the plaintiffs to make the Attorney-General, as representing the general public, a defendant.—("Daily Mail.")

CYPRIPEDIUM ORION.

ONCE again the great firm of Veitch & Sons, Ltd., Royal Exotic Nursery, Chelsea, has sent forth a new *Cypripedium* that deserved recognition and got it in the form of an award of merit from the Orchid Committee of the Royal Horticultural Society on the 14th inst. *C. Orion* (fig. 31) is a hybrid that resulted from a cross between *C. concolor* and *C. insigne*, and it is of chaste beauty. The ground colour is cream throughout, deeper in the dorsal sepal and flushed with rose in the petals. The spots over all are crimson, but large on the dorsal sepal and minute on the pouch. The flowers measured $3\frac{1}{2}$ inches across, and partake largely of the character of *C. insigne*, the foliage favouring *C. concolor*.

LÆLIA ANCEPS.

THIS most useful and beautiful winter flowering Orchid will by now have passed out of flower, and will perhaps need attention, either by top-dressing or putting into larger receptacles. After the removal of the spikes, the plant should be allowed to become gradually dry, and be kept on the dry side till young roots are observed to be pushing, when those that require larger pans or baskets (pans I prefer) should at once be attended to, also those that need top-dressing or re-surfacing.

As these plants require when in active growth a large quantity of water, the drainage must be perfect. I have found peat fibre, with all the fine particles taken out, and the same quantity of living sphagnum moss, with some pieces of soft brick about the size of walnuts added, to answer admirably for them. After being potted or re-surfaced, the plants should have no water till the roots are in active growth; a syringing between the pots, pans, or baskets will be quite sufficient to prevent shrivelling.

Lælia anceps succeeds in an ordinary intermediate house, or even a warm greenhouse, where an abundance of light and air can be afforded. When in active growth too much water can hardly be given, but during the time of rest a small quantity will suffice. The plants will stand a fair amount of sunshine, some people in fact using little shading, but I am of the opinion that it is advisable to prevent scorching and to keep the foliage in good condition.

Beautiful as is the typical flower, the most attractive are the white varieties, which when they become thoroughly established and strong are quite as free flowering as the type, as a plant of *L. a. Sanderiana* before me with eight spikes and thirty-two flowers testifies. The most beautiful of the white varieties are the true form of *Dawsoni*, *Amesiana*, *Sanderiana*, *Schröderiana*, *Stella*, *Williamsi*, and *Virginalis*. No plant is more interesting or produces flowers at a more useful time, or will better repay the time devoted to its culture.—J. BARKER, *Hessle*.

ONCIDIUM PECTORALE.

THIS is one of the most charming of the Brazilian *Oncidiums*, and it is a pity it is not more plentiful. The pretty spreading panicles of golden yellow and chestnut brown flowers appear in the middle of winter, and last a long time in perfect condition. The habit is rather dwarf, and it should be grown on trellis rafters in shallow baskets without too much compost about the roots. Although introduced many years ago the number of plants in cultivation has never been large; indeed, it was for many years practically lost to cultivation.

ONCIDIUM CHEIROPHORUM.

There are few prettier winter-flowering *Oncidiums* than this, and when well grown it is also one of the most free-flowering. The habit of the plant is tufted, the pseudo-bulbs small, and the flower spikes grow usually less than a foot high. The individual blossoms are about half an inch across, bright yellow with a paler coloured lip, and a large number of these are produced on a spike. The plants being so small, large pots or baskets are plainly unsuitable for them, for they could never produce roots in sufficient strength or number to push through the amount of compost needed. Many growers make this mistake of giving too much room to these small-growing kinds.

What they require is small pans with only an inch or two around the plant, while small specimens must not be separately potted, but simply massed and given suitable sized receptacles. In this way one prominent Orchid grower at least succeeds well with it, fine plants so grown being often exhibited by him. It is necessary to avoid thickening the compost unduly in this mode of culture, but it makes most beautiful little specimens where they do well. The slightly larger surface of the compost conduces to a more regular state as regards moisture, and thus the little roots are protected in a measure from

rapid fluctuations. The ordinary compost, consisting of about equal parts of peat fibre and sphagnum moss, with ample drainage, and a few small bits of charcoal and crocks, suits it admirably.

Coming from considerable elevation in its native place, *O. cheiroporum* likes during summer a cool airy structure, where ample moisture is present, and the heads are shaded from bright sunlight. During winter the house ought not to fall below 50° or thereabouts, this as a matter of fact being low enough even for the coolest Orchids, though in the majority of places they are kept cooler. In summer, of course, they cannot be kept too cool; in winter they must be brought right up to the glass, so that every ray of light during the dull sunless days reaches them.

Watering is necessary all the year round, for though towards late winter and early spring not much growth will be going on, the tiny bulbs must not be dried, or they soon shrivel, and the growths springing from their bases will be weak and spindly. It will be noted by the above that no special difficulty will be found in the culture of this pretty *Oncidium*, but all the season through unremitting care

FIG. 31.—CYPRIPEDIUM ORION.

to the details as they become necessary. Insects are not often troublesome, except in collections where other and dirty plants are kept in its vicinity; here scab may put in appearance, and thrips damage the young growth, but these will be got rid of by the usual means.—H. R. R.

— NITRATE OF SODA.—As a forcing food for the foliage parts of plants nitrate of soda does not stand in any need of an advocate to day. Mons. Paul Vincéy, Professor of Agriculture for the Department of the Seine, France, publishes the following as the results of his experiments:—The amount of nitrate of soda to be employed to the square mètre (39 square inches) is about 30 grammes if treating with such crops as Cabbage, 25 grammes for Potatoes, Carrots, and Lettuces. Nitrate of soda should not be mixed with manure, but be spread on the surface of the land to be harrowed in. Select for the application an occasion shortly before rain, or apply just before watering; but at the time of application care must be observed that the plants have not become wet in any way, because the fertiliser falling on the wet surfaces of the leaves burns them. Care must be taken not to give a larger dose than that indicated above, as an excess will act as a poison in plants. Nitrate of soda is often adulterated, for which the following tests are recommended. First, place a small quantity of the nitrate of soda in an iron cup and put that over the fire. If the sample is pure it will melt slowly and quietly in five minutes, commencing five minutes later to boil, emitting a bluish flame. If the nitrate contains any chloride of sodium or chloride of potassium mixed with other salts there will be a crackling and spluttering while on the fire. The second test is, half fill a drinking glass with nitrate of soda; fill the vessel with rain water and agitate or stir with a wooden spoon. The mass will be dissolved in a few minutes. If a few drops of a concentrated solution of nitrate of silver are now put in the liquor should become cloudy, resembling soapy water; but if a white precipitate is formed resembling curdled milk there is adulteration.—("American Gardening.")

ROYAL GARDENERS' ORPHAN FUND.

THE meeting at Anderton's Hotel on Friday afternoon last, when the subjoined report and balance-sheet were presented, was a comparatively large one. The work, under the presidency of Mr. W. Marshall, proceeded smoothly and satisfactorily. Amongst the best known participants in the meeting were Dr. Maxwell T. Masters (who unhappily does not yet look well), and Messrs. H. J. Veitch, W. Roupell, G. Assbee, H. J. Jones, C. Osman, R. Dean, A. Dean, H. B. May, G. Gordon, P. R. Barr, A. Outram, W. Denning, H. J. Cutbush, T. Lyne, W. H. Divers, W. Bates, G. J. Ingram, and J. Smith.

After reading the notice convening the meeting and other formal observances, the following report and balance-sheet, which were distributed to the members several days ago, were taken as read.

ANNUAL REPORT FOR 1898.

At the close of the eleventh year since the institution of the Fund your Committee are enabled to announce that it is gratifying to find that there is an increase in the annual subscriptions, though the Committee are compelled to admit that they have not hitherto received that measure of support from the gardeners of the kingdom that they had hoped for in the early days of the Fund. The financial support received has largely been derived from sources the existence of which was scarcely contemplated at the outset, such as receipts from the sales of flowers at horticultural exhibitions, the opening of gardens and plant houses to the public, concerts, &c. Gardeners' societies in particular have given a generous measure of support, which materially assisted the Committee in administering relief to the fatherless, when it was most urgently needed. In view of the number of applicants for the benefits of the Fund, your Committee do most earnestly appeal for the sympathy and support of the entire gardening community, and especially to that section of it for whose orphan children the assistance afforded by the Fund is solely intended.

There are now sixty-eight children receiving the benefits of the Fund, in addition to those to be elected this day. Most gratifying assurances are constantly being received from the mothers of orphan children, to the effect that the assistance rendered during the time the child was on the Fund proved of unspeakable advantage to many a struggling widow; and not less satisfactory has been the testimony borne to the timely and valuable aid rendered to some orphans in giving them a start in life after they had ceased to be chargeable to the Fund.

The total number of children who have been placed on the Fund

CASH STATEMENT FOR THE YEAR ENDING 31st DECEMBER, 1898.

Having inspected the Securities and examined the Books and Vouchers supplied to us, we hereby certify the above Account to be correct.

Dated January 21st, 1899.

The Chairman, in moving the adoption of the report and balance-sheet, was very brief indeed, as he considered that nothing remained for explanation. He commented, however, on the fact that gardeners, for whom the Charity was instituted, gave such surprisingly poor support, and considered they ought to do a very great deal more. Mr. G. Assbee seconded the motion, which was carried unanimously.

After the election of Treasurer, Auditor, and Committee, Mr. W. Marshall, on behalf of the Executive Committee, proposed Mr. Brian Wynne as Secretary, in succession to Mr. A. F. Barron, whose health compelled his resignation. Mr. R. Dean was the seconder, and there was not a dissentient voice—a fact that must be gratifying to Mr. Wynne, whose knowledge of the Fund and ability make him admirably suited to the position.

Mr. Harry J. Veitch then rose to propose a vote of thanks to Mr. A. F. Barron for his services since the inception of the Fund. He referred to his assiduous attention to duty from the commencement until now, and considered that the success that had been achieved must be largely accredited to Mr. Barron. He spoke of the general regret at the enforced retirement, and trusted that the benefit from the rest would assist recuperation, and that he would long be spared to assist the Fund with his experienced advice as a member of the Executive Committee. He

since its foundation is 103, and the total amount paid to the orphans is £6836 15s. Special grants in aid have been made this year to the amount of £18 5s.

The annual festival took place at the Hotel Métropole in April last, and the Committee were fortunate in securing the valued services of Charles E. Keyser, Esq., Aldermaston Court, Reading, High Sheriff of Berkshire, as their Chairman, whose forcible appeal in aid of the Fund assisted in realising the sum of £557 11s.

Your Committee have great pleasure in placing on record their high sense of the important services rendered to the Fund by the Treasurer, N. N. Sherwood, Esq., whose generous support of the charitable institutions connected with horticulture is so keenly appreciated by the whole gardening community; and they gave hearty thanks to their Auditors, Messrs. Martin Rowan and P. Rudolph Barr, for bestowing so much attention in auditing the accounts. Mr. Barr is the retiring Auditor, and is nominated by your Committee for re-election.

By the death of Baron Ferdinand de Rothschild the Fund loses one of its Vice-Presidents, and a generous supporter for several years past. The Committee recommend that C. E. Keyser, Esq., be this day elected a Vice-President to fill the vacancy.

It is with great regret that your Committee have to announce the retirement of Mr. A. F. Barron from the post of Secretary to the Fund through failing health. As one of the chief promoters of the Fund and its Secretary since its establishment, Mr. Barron has done much to further its interests, and merits the best thanks of all interested in gardeners and gardening; and in consenting to be nominated for election as a member of the Executive Committee Mr. Barron proves his devotion to the Fund, and his ready willingness to continue to afford assistance in carrying on the good work. The Committee unanimously express their sympathy with Mr. Barron, and their best wishes for his improved health and well-being.

Mr. G. W. Cummins has resigned his seat on the Committee, and Mr. T. Peed, Roupell Park Nurseries, S.E., has been elected to succeed him. The members of Committee who retire by rotation are Messrs. Cutbush, Laing, Lyne, Nicholson, Osman, Poupert, Smith, and Walker. These, with the exception of Messrs. Nicholson, Smith, and Laing, being eligible, offer themselves for re-election. The Committee nominate Messrs. A. F. Barron, Chiswick; J. Cheal, Crawley; and W. Howe, Park Hill Gardens, Streatham, for election this day.

The Committee, having advertised for a Secretary, have considered the numerous applications, and recommend Mr. Brian Wynne for election at a salary of £100 per annum.

(Signed) P. RUDOLPH BARR, } Auditors.
M. ROWAN.

proposed that an address be engrossed on vellum, and be presented to Mr. Barron, which, with the vote of thanks, after being seconded by Dr. M. T. Masters, was carried with acclamation.

The ballot for the election of pensioners resulted in the following being elected:—Alice Gilhorne Seaton, 375; Muriel Gutteridge, 373; Daisy Agnes Spong, 282; John Henry Donaldson, 256; James Henry Tanton, 250; Helen Macdonald Milne, 217; Isabella Emma French, 205; Vanda Mary Bartlett, 200; and Harry John Mason, 195. The unsuccessful candidates were Arthur George Wood, 190; Hilda Kathleen Mary Rogers, 189; Winitred Moxham, 160; Aaron Hall, 91; Arthur Gregory Stephenson, 65; Edward White, 63; John Baird, 41; and William Ernest French, 11. Two others, James and Eugenia Seegar, have left the country, and are thus placed beyond the benefit of the Charity.

The Executive Committee recommended that Rule v. should be altered to read:—

Line four, after the word "purpose," omit the words "All donations and legacies," and insert the following:—"All receipts, except legacies and donations specially given as such for investment, shall be considered as subscriptions, and be available for current expenditure. All legacies and special donations."

Rule xi. was also proposed to be altered as follows :—

Line five, after the word "require," make the following addition :—

"Not more than two children of the same family can be in receipt of the benefit of the Fund at the same time."

Both these propositions, after being duly seconded, were carried unanimously.

Now that the annual general meeting of this Fund is over, the new Secretary has been unanimously elected, the old one properly and warmly thanked, as well as put on to the Committee, and the election of nine children is over, it is to be hoped that there will be seen during the ensuing year a very great revival of interest in the Fund, and that we may see during that time an increase of some 500 gardener subscribers at least, for it is little less than a scandal that the gardeners of the kingdom, in whose interest specially the Fund was started, support it so indifferently. When it becomes a case of comparative indifference or "don't caredness," those who have been other than gardener subscribers naturally ask whether it is worth while to maintain the Fund longer. It was a deplorable fact that of nineteen children nominated for election this year, not in one case had the deceased father been a subscriber, even of so small a sum as 5s. per annum.

To what is this indifference on the part of gardeners due? Can anyone explain it? Will any who are discontented even anonymously tell plainly the reasons why they refuse to become subscribers? It would help so much to the desired end were complaints or difficulties, if such exist, made fully known. At the recent election out of nineteen children nominated two (German), having left the country, became ineligible, and one other was rendered such by the passing of the amendment to Rule xi, which now invalidates the nomination of any third child of the same family. Thus, the nominations being reduced to sixteen, and nine were elected, it is seen that only seven failed, and probably all these will be elected next year, as their present votes count then. —A. D.

THE HISTORY OF THE PELARGONIUM.

THE history of the Pelargonium is most interesting, and many readers of the *Journal of Horticulture* may be unfamiliar with it. A correspondent, "G. H. W.," asks us to give this history in brief. We think, however, both for his and other readers' benefit, we cannot do better than to give the text of a lecture on the subject that was delivered before the Royal Horticultural Society by the late Mr. Shirley Hibberd in 1880.

The Pelargonium affords a subject large enough to occupy as many hours, days, or even weeks, as the mere moments I shall devote to it on the present occasion. It is fortunate I am not bound to mention Geraniums, for, if they are of less importance than Pelargoniums they take us further back in time, and to do justice to them we should have to rummage amongst the old books and fish up some very curious memoranda. But the mention of the Geranium renders it necessary to begin with definitions. A Pelargonium is not a Geranium, although often so called. The true Geraniums are for the most part herbaceous plants inhabiting the northern hemisphere, and the Pelargoniums are for the most part shrubby or sub-shrubby plants of the southern hemisphere. Let us for a moment wander amongst the pleasant slopes of Darley Dale in Derbyshire, or by the banks of the Clyde or the Calder. We shall in either case be rewarded by seeing vast sheets of the lovely Meadow Crane's-bill, *Geranium pratense*, a true Geranium, and one of the sweetest flowers in the world. In the rocky recesses of Ashwood Dale, or on the banks of the "bonny Doon," we may chance to see in high summer a profusion of the Herb Robert, *Geranium Robertianum*, with pink flowers and purple leaves, a piece of true vegetable jewellery. And, once more, I invite you to an imaginary journey, and we will ride by rail from Furness to Whitehaven in order to behold on the railway bank, more especially near St. Bees, a wondrous display of the crimson Crane's-bill, *Geranium sanguineum*, which from July to September forms solid sheets, often of a furlong in length, of the most resplendent colour.

Now let us fly to the other side of the globe and alight in the vicinity of the Cape of Good Hope, say on the vast desert of Karroo, where there is much sand, much sunshine, and little rain. Here, in the midst of desolation, the world is rich with flowers, for the heathy scrub that occurs in patches, glowing with many bright hues, consists in part of wild Pelargoniums, which often take the form of miniature deciduous trees, although in the valleys nearer the coast, where more rain falls, they are evergreen bushes.

Very different in their characters are these two tribes of plants, and they are not less different in their constitution and aspects. We may regard the Geraniums as herbs of Europe, and the Pelargoniums as miniature trees of Africa. When we examine the flowers we find the five petals of a true Geranium of precisely the same shape and size; but the five petals of a Pelargonium are not always so, for sometimes the two topmost are the largest and stand apart from the rest. A Geranium has ten stamens, and a Pelargonium has only seven. These numbers are not constant, but the exceptions are of no consequence in a general statement of the case. When all is said that can be said about the differences and resemblances of the several families of Geraniaceæ, there remains only one constant and unfailing test of a

true Pelargonium, and that is the nectariferous tube immediately beneath the flower, and running down one side of the flower-stalk.

The best short summary of the history of the Pelargonium I have met with is in the *Gardeners' Chronicle* of October 2nd, 1841. It gave me a clue that I wanted to the first-known Pelargonium as an inmate of an English garden. It speaks of one known to Gerarde, but there is no mention of in the Gerarde of 1597. However, at page 948 of Johnson's Gerarde of 1633 is a record of a plant called *Geranium indicum*, "as of late brought into this kingdom by the industry of Mr. John Tradescant;" and the author adds, "I did see it in flower about the end of July, 1632, being the first time that it hath flowered with the owner thereof." The plant figured by Sweet as *Pelargonium filipendulifolium* (L. 85) is a variety of *Pelargonium triste*, which is identical with the Indian Geranium of Johnson's Gerarde. Thus we determine that the first flowering of a Pelargonium in this country occurred about 250 years ago.

Here it may be proper to remark that there are a few true Pelargoniums that are not natives of the Cape of Good Hope. *P. canariensis* is a native of the Canaries; *P. australe* comes from the Australian continent; *P. cotyledonis* is found wild in St. Helena; *P. Endlicherianum* is Asiatic and almost European. There are two or three species in Abyssinia. But *P. triste* is a Cape plant beyond a doubt, and it is most agreeable to know that our first Pelargonium was brought into the country by John Tradescant, of whom Parkinson speaks as that worthy, curious, and diligent searcher and preserver of all Nature's rarities and varieties. It was in all probability amongst the treasures acquired in his voyage to Barbary, in the fleet sent out against the Algerines in 1620. When, in 1629, he became gardener to Henrietta Maria, Queen of Charles I., this plant was in his famous collection at Lambeth, and was thence sent forth as the pioneer of the Pelargoniums and the Pelargonium Society. As the Cape was discovered in 1497, the plant had 123 years to complete the journey to the Mediterranean, and no doubt had the help of Portuguese traders in so doing.

It is singular that John Tradescant, who was an Englishman, born in Worcestershire, and probably of French extraction, was always regarded as a Dutchman. It is singular in this connection, because subsequent to his introduction of the first Cape Pelargonium, the Dutch were certainly the introducers of a dozen or more species that soon after came into Europe. In Dr. James Sherard's wonderful garden at Eltham there were in 1732 half a dozen species. In the second edition of Miller, published 1733, there are twenty species of African "Geraniums," and these are all Cape Pelargoniums. This brings us to the publication by Linnæus of the "Genera Plantarum" in 1737, and the "Species Plantarum" in 1753, when the twenty-five species of Pelargoniums known to him were described as Geraniums for the last time in any work of high authority. In 1787 L'Heretier distinguished them by the signs I have already mentioned. In the "Hortus Kewensis," published in 1812, as many as 102 species and hybrids are described as then in cultivation at Kew, and the list includes *triste*, *grossularoides*, *zonale*, *inquans*, *lateripes*, *peltatum*, *grandiflorum*, *quercifolium*, and *fulgidum*.

The splendid garden varieties of Pelargoniums that afford us so much delight are in a certain sense the creations of human skill. Nature never needed such things and did not trouble to produce them. They are the products of careful systematic hybridising and crossing, and they represent the talent and perseverance of the florists during a period of sixty-five years—a period so brief considering what has been accomplished that it shrinks to a moment when we compare the original wildings with the splendid flowers of to-day. In the year 1815, or thereabouts, the amateurs began to cross the species, and one of the leaders in this delightful work was Sir Richard Colt Hoare, who obtained a considerable number of beautiful hybrids. The work was taken up with more serious views by Mr. Robert Sweet, the author of a number of valuable illustrated works, comprising one in five volumes devoted to the Geraniaceæ.

The large-flowering or florists' Pelargoniums are reputed to be the offspring of *P. speciosum*. It must be evident to every cultivator of these flowers that the blood of a score or so of species is mingled in them. *P. speciosum* was introduced in 1794, but it has no place under this name in Sweet or the "Hortus Kewensis." It is variously described as producing purple and white flowers, and can scarcely be said to have a history. If the question be asked, What is *Pelargonium speciosum*? I must refer to Sweet's description of *P. involneratum*, No. 33. He there refers to *speciosum* of Andrews as identical with his own *superbum*, and he puts the *speciosum* of Willdenow out of court altogether. It is likely, I think, that *P. spectabile* (136), a hybrid raised from *P. cucullatum* and *P. ignescens*, and *P. involneratum* (33), raised from *P. cucullatum* and *P. superbum*, were the founders of the florists' race. Certain it is that these typical kinds were endowed with the capability of varying indefinitely, and with a plastic constitution rendering them possible sources of innumerable floral surprises. It is scarcely an exaggeration to say that amongst the true hybrids there are at least fifty that might be the parents of our exhibition race. But to clear up the point is impossible, for in very few instances did the early raisers keep any record that could be referred to for settling questions of pedigree.

The first variety figured as a proper florists' flower was called *Geranium grandissima*, raised by Mr. Widnall of Grantchester. The portrait of this variety appeared in the "Floricultural Cabinet" of September 1st, 1834. It was a pretty flower, with rich dark top petals and warm blush-tinted under petals; but the small size and poor form would exclude it from any collection of Pelargoniums in the present day. What a marvellous advance on this do we behold in the latest flowers of the present day.

(To be continued.)

NEW DAHLIAS OF 1898.

NEW Dahlias, like new Chrysanthemums, continue to be distributed every year, and the tendency is mainly towards the Cactus section, and many of the new varieties sent out in 1898 are of exceptional merit. One very noticeable fact is the decline of the decorative Dahlia; few new ones are sent out, and only a minimum of these are bought, although some are beautiful and most useful for cut flowers. I raised some thousands of seedlings this year, and it went against the grain to throw away so many that ten years ago would have meant a small fortune. Many of the new Cactus sorts are really decorative in habit, having fine long stiff stems that carry the flowers well above the foliage.

We are still waiting for a pure white true Cactus Dahlia, and a white Glare of the Garden. In Miss Webster I thought we had the former, and some of the flowers I have had perfectly white and fine form; still it is not the thing, and Keynes' White is not a white but a cream, and sometimes not of first-rate form, besides often coming semi-double, like Mrs. Peart. The best of the Cactus of last year, so far as I have tried them, are given below:—

Night.—Very dark maroon, good shape, free flowering, perfect habit, about 4 feet high.

Keynes' White.—Of fine form and habit, 4 feet high, and very free; the best approach to a true white Cactus Dahlia to date.

Britannia.—A charming variety with long twisted petals of a salmon pink shade, free, long stiff stems; sure to be a favourite.

Arachne.—A distinct break, reminding one of the old Maid of Kent, or W. T. Aberly. Each petal is white with a crimson edge, long pendulous stems; delightful for cut flowers, height 4 feet.

Alfred Vasey is one of the best, having long stems, and the flowers carried above the leaves; a fine plant for garden decoration; the flowers are of medium size and most useful for cutting; the colour is bronzy pink, height 3 feet.

Capstan is very similar to the above in habit and style of flower; colour a soft brick red; a fine decorative Cactus variety, 3 feet high.

Mrs. John Goddard.—One of the very best; a glowing crimson-scarlet flower of fine shape, first rate for any purpose; 4 feet high.

Mary Service.—A novel colour of salmon pink and yellow, will be a great favourite; fine habit; 3 feet high.

Fulka.—A good flower of undecided colour, sometimes rosy crimson, but pales quickly with age; free bloomer, and dwarf habit.

E. J. Deal.—A magnificent colour, bright scarlet, but shy bloomer and very tall, nearly 6 feet.

Laverstock Beauty.—Colour vermilion; a bright useful flower. The plant has a good habit, but is not free flowering; stiff stems; 4 feet high.

Casilda.—A delightful shade of sulphur yellow, tinted with pink on the older petals; very free, but has not long flower stems, and has a tendency to be semi-double.

Daffodil.—Sent out with a flourish to beat that best of all Cactus Dahlias, Lady Penzance; but has not sustained its reputation. The blooms are fine, but have short stems.

Ethel.—Lighter in colour than the preceding, but is a splendid shaped flower, but not very free; 5 feet high.

Octopus.—A monstrous flower, sometimes pure white, often suffused with lilac; free flowering, and will be a favourite with some people.

Tillie.—A dwarf variety, growing 2½ feet high; salmon, suffused with rose; a nice colour, but not a very good Cactus flower, although certificated by the National Dahlia Society.

Standard Bearer.—Fiery scarlet; good and free flowering, first-rate habit; 3 feet high.

Ruby.—As its name suggests is ruby red; a free flowering sort with stout stems, good habit; 4 feet high.

Oaklands.—Salmon rose; True Friend, dark crimson; W. J. Frost, rich crimson; and Eileen Palliser, yellow, are fairly good; so also are King of Siam, dark; Mrs. Scrase Dickens, yellow; Profusion; and many others; but the best are those I have described. These were seen in the South and in the North under widely different conditions, and received a good test.

Not so much attention is devoted to the raising of Show and Fancy Dahlias now, as the Cactus sorts take all the raiser's attention. Yet the double type will give a far better effect in a garden than all the quaint Cactus-shaped sorts. Last autumn I saw an acre of Cactus varieties growing alongside of a quarter of an acre of the double type. On the doubles there were thousands more blooms than on four times the quantity of plants of the Cactus.

Harbinger.—A lovely shade of peach, over the medium size, and of splendid form, was raised by that veteran florist, Mr. G. P. Harris of Orpington, and is one of his best varieties.

Muriel Hobbs.—Fine yellow, of splendid petal and outline; a first class variety.

J. R. Tranter.—A fine terra-cotta in colour, is also excellent.

Nansen.—A fancy variety, orange scarlet tipped with gold; a neat shaped flower.

Some delightful single Dahlias continue to be sent out, but the demand is decreasing yearly, which is unfortunate, as plants of single Dahlias make delightful objects in the garden, even if the flowers are not so much used for cutting. Duchess of Marlborough, white edged with crimson; Colton Beauty, white margined with yellow; Mrs. Phillip Hoare, rich velvet maroon; and Janet Braes, magenta and crimson, were some of the best of last season's varieties.

Pompon Dahlias still retain their popularity. The small flowers lend themselves so readily for cut flowers that the Cactus varieties do not have the same effect on them as on the other classes.

Agate.—Sulphur with a white edge; is a neat little flower, and grows 4 feet high.

Nellie Bromhead.—A beautiful mauve; is one of the prettiest of Pompons, and will be sure to stay for years; dwarf habit and free.

Hypatia.—A nice flower; amber, and yellow edge; very distinct, and of good shape; 3 feet high.

Zoe.—Yellow, tipped with white; is a pretty Fancy; 3 feet high.

Several good single Cactus were sent out, but all by one firm, who make a speciality of this beautiful section. I hope to devote a few lines to all the varieties in this class shortly.—GEORGINA.

THE YOUNG GARDENERS' DOMAIN.

FORCING LILY OF THE VALLEY.

No flowers are more useful during the winter months than the Lily of the Valley from forced crowns or clumps. Single crowns are greatly to be preferred to imported clumps, for when the latter are employed few flowers are obtained, and those produced are inferior in quality. Single crowns when well grown provide splendid spikes of blooms equally all over the pot, which easily repay the little extra cost at the outset. About fifteen good crowns can be placed at equal distances apart in a 5-inch pot, after removing the roots to within 2 or 3 inches of the bud, and any soil may be employed, as few roots are made, but it must be made firm and the crowns kept above the soil. Place the pots in a cold frame and cover with cocoa-nut fibre refuse or moss to swell the crowns, taking care not to overwater, as that causes decay. From this position bring them gradually into heat, and keep the moss over them till the crowns burst. The pots can then be plunged in bottom heat of about 90°. The plants may be flowered in two or three weeks, but when thus hastened very little foliage may be produced. It is better to have the pots some distance from the glass, as if too close the spikes are short and stumpy.—F. SIDWELL.

GLADIOLUS THE BRIDE.

THE blooms of Gladiolus The Bride are very useful where decorating, bouquet and wreath making are done largely, especially if they are flowered early; therefore I will write a few notes as regards their culture. The bulbs may either be grown in the open or in pots. For early flowers pot the bulbs at the end of September in 6-inch clean, well-drained pots, allowing room for watering, the compost consisting of two parts loam, one part sweet horse droppings and leaf soil, with a good sprinkling of sand. After the bulbs are potted plunge the pots in frames, using fine ashes for that purpose.

When root action has commenced, a few pots may be taken in, if required early, affording them a temperature of 65° to 70° at night, 70° to 75° by day; be sparing with water at this stage, only applying when it is necessary. When the plants are showing their flower spikes, it will be found necessary to place a few stakes around the pots, and also pieces of raffia to support them, and to remove them to a cooler house with a night temperature of 58°. At this stage a little weak liquid manure will be beneficial to them, increasing its strength gradually. Thomson's Vine manure mixed with clear water will be found a good stimulant, using a small handful to 2 gallons of water. To maintain a succession of flowers, take in the pots at intervals, treating as before stated.

Turning to the outdoor culture, the plants can be grown either in beds or patches. In the latter case they make a grand effect if planted near the front of herbaceous borders. If beds are required the rows should be a foot apart, and the bulbs 2 inches or 3 inches in depth. Early in March is a very suitable time for planting, and in doing so, if the soil is rather poor, apply some well decayed manure to it. When the plants appear above the surface, and the rows are distinctly seen, hoe lightly between them, to destroy any weeds, and also to loosen the surface soil. If the weather becomes hot and dry watering should be attended to, after which give a light mulching of Mushroom bed refuse, as by so doing the bed will be kept moist for a longer period.—P. R.

IXORAS.

FEW plants requiring stove temperature are more valuable both for exhibition or decorative purposes than Ixoras. Large specimens with rich deep green foliage and noble heads of flower have an imposing effect, while smaller plants, with from one to half a dozen trusses, can scarcely be excelled during their flowering period.

Ixoras can be propagated by cuttings formed of short-jointed half ripened shoots, inserted firmly in thumb pots in a compost of peat, leaf soil, a little fibrous loam, with a liberal portion of sharp silver sand. The pots must be plunged in bottom heat in a stove or propagating pit, and in a few days roots will be emitted. When these reach the sides of the pots transfer them into a larger size, and eventually into 5-inch pots, using the same compost as before. Healthy medium sized plants in these pots, carrying half a dozen flower trusses, are very valuable for many purposes of decoration. Future shifts must be at the grower's discretion, according to the sizes of plants required; but too much soil is never advisable, as it may become sour and unhealthy plants be the result.

Liquid manure may be afforded occasionally when well established. Too much water must not be given to the plants in winter time. During the

growing period give ample heat, and syringe freely when required, and the pots should be half plunged in a hotbed. Straggling shoots must be stopped to give two or three shoots instead of one. This treatment should continue until September, with a little shade from bright sun. The pots ought then to be placed nearer the glass, and in full light, syringing being resorted to at times, but must be gradually discontinued, and water at the roots also lessened, though never so as to cause the plants to droop. The object of this is, of course, to ripen the shoots formed. With the moisture lessened the temperature may be allowed to fall to 60°. A rest is thus given in the dull season.

About March or earlier the temperature may be gradually raised, and the pots be plunged in a sweet hotbed, with openings below to insure drainage. Water at the roots will be more needed, and the syringe should be used before the flower trusses show, when a drier and cooler atmosphere should be given to preserve the blooms. Under the foregoing treatment *Ixoras* have done splendidly, and have fully repaid all the attention given during the growing and ripening period.—INTERESTED.

FRUIT FORCING.

Cucumbers.—The plants raised from seed sown at the new year and transferred to the ridges or hillocks in the Cucumber house need not be stopped until they have extended two-thirds up the trellis. Train the laterals about 1 foot distance apart, and do not stop them until they have extended about two-thirds across their allotted space sideways. A vigorous growth is thus secured, and the plants will crop much better and longer than those which are pinched from near the bottom of the trellis with a view to early fruit. If the latter practice is followed care must be taken not to overcrop the plants, or the growth will be stunted, and not enough made for a successional and regular supply of fruit.

Winter Fruiters.—As the light and sun heat tell advantageously a greater supply of atmospheric moisture is needed, keeping the evaporation troughs charged with liquid manure, or sprinkle the paths occasionally with it at closing time, damping with water in the morning and early afternoon. Supply top dressings of fresh lumpy loam at fortnightly or three weeks' intervals, and sprinkle on each square yard a handful of a mixture of bone superphosphate and soot in equal parts by measure. Thin the fruits well, remove superfluous growths, bad leaves, tendrils, and male blossoms, stopping the shoots one joint beyond the fruit, avoiding overcrowding. Maintain a night temperature of 65°, 70° to 75° by day, advancing to 80°, 85°, or 90° from sun, and closing early so as to run up early in the afternoon to 95° or 100°.

Vines.—*Early Forced in Pots*—The Vines started early in November, and being strong well-ripened canes, have, under proper management, the Grapes in an advanced state, and soon will be taking the last swelling. This occurs with the colouring, when they swell more than at any other stage, therefore supply fresh top-dressings of turfy loam or lumpy well-decayed manure, with a sprinkling every ten days or fortnight of superphosphate three parts and one part powdered saltpetre, mixed. This not only feeds but encourages root action, and the roots absorb liquid manure, which should be supplied warm, copiously and not too strong. Maintain a genial condition of the atmosphere by damping the paths and walks two or three times a day, especially at closing time, which should be sufficiently early to run up the temperature to 85° or 90°.

Stopping, Tying, and Regulating Shoots.—The growth in houses started a few weeks ago will be sufficiently forward for disbudding, but not attempting it before the best breaks can be discerned. The operation should be performed gradually, removing the weakest and worst placed first, and ultimately leaving no more growths than there is space for the full exposure of the foliage to light, always retaining the most promising for fruit. Stopping should take place at one joint beyond the bunch where the space is limited, but two joints ought to be left where there is room for lateral extension. Tie the growths before they touch the glass, bringing them down carefully, as they are liable to break. Allow sufficient room in the ligature for the swelling of the shoots, and loosen all those that are too tight.

Vines in Flower.—Cease syringing, yet avoid a very arid atmosphere, and prevent condensation of moisture by a little ventilation constantly without causing a draught. Temperature 60° to 65° at night, 70° to 75° by day artificially. Carefully fertilise shy-setting varieties, brushing the bunches lightly with a camel's-hair brush, and then follow with some charged with pollen collected from free-setting sorts, such as Black Hamburgs. Fertilisation is imperative in the case of Muscats, attending to it on a fine day after the house has been ventilated a short time, and always when the "caps" part easily from the tips of the flowers, as then the stigmas are ready to receive the pollen.

Thinning Grapes.—Never allow this work to get into arrear, but thin free-setting varieties as soon as they are fairly out of flower, taking out the smallest berries first, and then going over the bunches again, so as to leave only sufficient berries to form a compact bunch, each berry being allowed space to swell to its full size without wedging or losing its natural

form. This requires the exercise of a little judgment, and can only be acquired by experience. Muscats and all shy-setting varieties should not be thinned until the properly fertilised berries can be distinguished, as they may by their taking the lead in swelling, whilst the unfertilised remain almost stationary.

Feeding.—After setting and thinning the Grapes swell fast, and should be accelerated by judicious applications of liquid manure, encouraging surface roots by light mulchings of lumpy manure, such as sweetened horse droppings, and sprinkling on each square yard a small handful of the mixture advised for Vines in pots. Attend to watering as required, not having stated times, but always make an examination of the border, and supply tepid water whenever necessary, but then only, and always sufficient to moisten the soil down to the drainage. Overwatering is even worse than too little, as it makes the soil sodden and sour, and shanking follows. Maintain a genial condition of the atmosphere by damping the floor and border in the morning, at closing time, and in the evening. Make the most of sun heat by early closing, running up to 85° or 90°, and this will maintain a good temperature into the night, when it should gradually fall to the minimum temperature of 60° to 65°. Admit air in the morning before the sun has raised the temperature more than 5° to 10°. This should be done without lowering the temperature, and the Vines will be saved from scorching.

THE KITCHEN GARDEN.

Cropping the Ground.—The rainfall has been exceptionally heavy, and when a change takes place the ground in many instances will be found slow in arriving at a suitable condition for cropping. Once more, then, the advice not to be in too great a hurry in sowing seeds and planting other crops is the best that, under the circumstances, can be given. Especially is this the case with cold clayey soils, and those who have to deal with these ought to forward Peas, Beans, Cauliflowers and Lettuces, by sowing under glass, planting out in due course.

Cauliflowers.—Good late Broccoli is none too plentiful, and if the mild weather continues the supply will not hold out so late as usual. This being so there is all the more necessity to take extra care of autumn-raised Cauliflower plants. These transplant better out of 4-inch pots than they do from boxes, and a little time will be gained by establishing in these pots in gentle heat under glass, taking care to harden them before they become badly root-bound, planting in hand-lights across the garden or in a rough deep frame over a bed of soil and manure. They will not bear forcing, and must not be unduly coddled. If seed of the small early sorts are sown now in gentle heat they will germinate quickly, after which shelves near the glass in a cooler house or pit is the best place for the plants. When they have formed a rough leaf, pot singly or in pairs, and treat as advised in the case of the autumn-raised, only in this case a portion of the plants may be planted on a warm border and the rest in the open.

Lettuce.—A few or many plants of early and second early Cabbage and Cos varieties of Lettuce, raised from seeds sown in pans or boxes under glass now, should prove of service in keeping up the supply of salad. Avoid sowing the seed thickly, and raise the plants in gentle heat. Harden early, and prick out in sheltered nursery beds, where a portion of the plants may be left to heart-in, transplanting the rest when large enough to sunny well-manured borders.

Garlic and Shallots.—Directly the ground can be got into a suitable condition roots of both kinds should be planted. It must be remembered that single divisions (cloves) will grow into large roots, while the larger-sized roots, planted whole, will split up during the growing season. Press them into well prepared firm soil, rather more than half burying them, and if disposed 6 inches apart, in rows 9 inches to 12 inches asunder, this will be allowing ample space. If Parsley is raised under glass, with a view to having early gatherings of leaves, this may eventually be dibbled out midway between the Garlic and Shallots, in which case the rows of the two latter should be fully 12 inches apart.

Seakale Propagation.—Where young roots are lifted and forced a fresh stock of plants has to be raised every season, and early propagation means a good start towards obtaining the desirable strong roots. When the roots are lifted for forcing all the stronger thongs unavoidably or purposely snapped off should be saved, and stored in moist soil or sand. These may be cut into 3-inch or 4-inch lengths, marking the smaller end, which is to be the rooting end, by slicing a small piece off it. Store the cuttings thickly to their full depth in boxes of fine soil or common sand, and arrange them in cool house, frame, or shed for the present. By the time they have formed a few roots and commenced top growth the ground ought to be ready for their reception, and planting-out take place.

The Mushroom House.—Mushrooms are impatient of much fire heat, and whenever the weather is mild it should be dispensed with as much as possible. A temperature of 55° answers well, and a newly formed bed will often serve to keep up sufficient warmth. Beds that did not start producing before midwinter or as soon as expected, may yet do good service. Examine them, and if found cold and damp with few or no traces of the spawn having run, they may well be broken up, and their room devoted to fresh beds; but if dry and apparently overrun by a white mould, the chances are a good crop of Mushrooms may yet be forthcoming. Apply enough tepid water through a rose to well moisten the soil and manure, more than one application being necessary to accomplish this, afterwards covering the bed with 6 inches of stained straw or litter. Watering with tepid water impregnated with salt will sometimes put new life into an apparently exhausted bed, especially if this can be supplemented with the heat from a fresh bed formed below.

THE BEE-KEEPER.

CONDITION OF STOCKS.

OWING to the mild weather which on the whole has prevailed throughout the country during the past winter many of the stocks may now be short of stores. This will be more apparent in colonies that were not fed last autumn. The fine bright weather experienced during early autumn, and the large amount of honeydew that was still on the trees, kept the bees breeding much later than usual. The result was a large consumption of stores. This did not seriously affect colonies that were in an ordinary hive on which was placed a top storey of full-sized frames, a crate of sections, or shallow frames. These would have ample stores and to spare. Others, which from various causes were not in this condition, owing to the bees being confined on a given number of frames in the body of the hive, will now require attention if the best results are to be expected from them during the coming season, and as a query comes to hand from a new reader of these notes *re* candy and how to make it, a few words on this subject may be of interest.

MAKING CANDY.

Many bee-keepers find a difficulty in making a fine-grained, moist, soft candy, although the operation is to an experienced man very simple. We failed in our first attempt, owing to having too strong a fire; there is now no danger of this, as we always use a paraffin stove. We would strongly recommend others to do so in preference to an open fire grate, as they are clean, and the heat may be regulated, so that there is no danger of the sugar boiling over, which it is liable to do when the fire is too strong. We prefer a fine, granulated sugar, and if the right kind is obtained it will be ready for taking off the stove after it has been boiling for two minutes. Another kind of sugar, very similar in appearance to the above, may be used, but it will require to be boiled for at least ten minutes.

A brass or enamelled iron preserving pan should be used, into which put 12 lbs. of sugar, two imperial pints of water, and two teaspoonfuls of cream of tartar. Set on the stove or on a clear fire, stirring constantly to prevent burning until it comes to the boil. Turn the burners slightly down, or withdraw from the fire, to prevent boiling over until the mass begins to settle down to boil, which is readily known by the frothiness. Continue stirring, and have ready a cup of cold water for testing it, and with a teaspoon lift out a little syrup and drop it into the water. If it lie at the bottom of the cup, so as to lift like very thick paste or putty, it is just right, and ready to be removed from the fire. If too much boiled the syrup will be hard and crisp in the water. This can be remedied by adding a little water to the syrup after its removal from the fire.

The pan should then be placed in cold water to hasten the cooling process. Whilst this is taking place prepare some shallow dishes (an ordinary saucer answers the purpose admirably), and into these place some sheets of thin paper slightly larger than the saucer, or whatever is used. When all is in readiness return to the pan of cooling liquor, which should now be kept constantly stirred. At first it will be dark in colour, but as it cools it will have a greasy appearance, gradually getting whiter and stiffer. When it has become somewhat stiff, but not too much so, or there will be a difficulty in getting it out of the pan before it sets, pour into the shallow dishes prepared for that purpose and allow it to cool. The result will be a fine-grained soft candy which will be taken readily by the bees. The candy may be removed from the saucers as soon as it is cold and well set.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Physianthus albens (*Aspirant*).—As the issue containing the illustration of the white Bladder-Bloom is out of print we are reproducing the block on page 149. The spray depicted was sketched from a specimen exhibited before the Royal Horticultural Society in 1885. The plant is very seldom seen in cultivation.

Black Currant Bud Mite (*G. P.*).—There is not the slightest doubt but that your bushes are attacked by this insidious foe. If the plants are badly infested we should lift and burn them, afterwards heavily liming the ground. You cannot do better than follow the advice given to "T. D." on page 38 of our issue of January 12th, 1899.

Worms in Soil (*J. C.*).—The small lumps of earth swarm with "white worms," *Enchytraeus Buckholzii*, which attain a length of about 1½ inch, and injure plants by sucking the fine root hairs and thus set up decay, when they feed on the dead matter. The worms also produce a sodden condition of the soil, due to working and feeding on the organic matter, and cause ill-health, if not actual decay of the roots of plants grown in it. They are generally most abundant in soil containing a large amount of vegetable remains, such as turf. The worms readily succumb to dressing with quicklime, using about ½ lb. per square yard, slaking the lime and applying when cool, always in an apparently dry, floury condition. The watering will carry some of it into the soil, and the worms reached will be destroyed. Lime water made by placing a peck of quicklime in a tub, pouring on 30 gallons of water after slaking, leaving for a week if possible, and using the clear liquid for watering the plants, is valuable, but must not be used at frequent intervals. The worms also yield to kainit, applying in solution, 1 oz. to a gallon of water. Both the lime and the kainit will benefit the Tomatoes, taking care not to make the ground sodden by needless applications. The soil, however, ought to have mixed through it before using for plants 2½ per cent of air-slaked chalk lime, partly to make an end of the worms, and partly to supply that element for reducing the organic matter into assimilable plant food.

Grapes and Peaches in the Same House (*C. H.*).—These have been produced more or less satisfactorily in the same structure during the last fifty years to our knowledge, the Vines in most cases occupying the roof and the Peach trees the back wall of the house—a lean-to facing south. The first structure we saw with both Vines and Peach Royal George and Nectarine Elruge trees in it had the Vines or rods 4½ feet apart, or one to each rafter, and 18 inches from the glass, the Vines (Black Hamburgh and Muscat of Alexandria) being spur-pruned. The roots of the Vines were wholly outside, and extended in sandy loam over 20 yards from the house. The Peach and Nectarine trees occupied the centre of the vinery, being trained to a sloping trellis fixed 6 feet from the glass. The Peaches and Nectarines were large, well coloured, and of good quality, ripe in July. The Black Hamburgh Grape ripened in August and the Muscat of Alexandria in September. In 1897 we saw Peaches and Grapes grown in a lean-to house, the Peach trees on the back wall and the Vines 6 feet apart on the roof. The Peaches, ripe early in August, were good in crop, large in size, and of first-rate quality, while the Grapes were colouring well and the crop a heavy one in medium sized bunches. The foregoing will give you some idea of what may be done, your case being better, as you propose planting the Vines on one side of the house and the Peach trees on the other. Still we do not approve of the mixed system, it being more satisfactory to have separate structures for each fruit.

Silico fluoride of Ammonium (*J. A. S.*).—The article is not in commerce, it being a preparation due to the genius of Mr. W. Mills, and by him first brought to notice in the *Journal of Horticulture* for the destruction of pests. Mr. G. Abbey had his supply from Mr. Mills, who would no doubt treat you in a similarly obliging manner. If you write to him, care of Editor, 8, Rose Hill Road, Wandsworth, we will forward the letter.

Seedling Hollyhocks (*W.*).—The better plan would be to transfer the seedlings into larger pots, growing them in the cold frame and hardening before planting during mild weather in April. This will give much finer plants and a better prospect of bloom this summer, there being nothing like a strong plant with plenty of active roots ready to lay hold of the soil without delay.

Planting Carnations (*Idem*).—The beginning of March is much too early to plant out yellow-ground and other Carnations wintered in a frame, as the winds are often very sharp and cold, thus stunting the "grass," especially as the winter has been mild. We should keep them in the frame, well ventilated, until April. If the weather prove mild during March the stock may be planted out, but we should not be in a hurry for the reason given, certainly deferring it until the middle or end of the month.

Vines Breaking Irregularly (*E. B.*).—It is not unusual for Vines of several different varieties in one house to start into growth unevenly, and even in individual Vines for some buds to break and others remain dormant, or not start until the others are well advanced in growth. This usually arises from indifferent ripening of the wood and an unsatisfactory condition of the roots. There does not appear to be anything wrong with the treatment, but 50° to 60° at night is a long range, yet the lower degree would not do any harm if it did not occur often, a few degrees not making much difference. Now that the Vines are coming into leaf the temperature should be kept at 60° to 65° at night, 70° to 75° by day, ventilating from 70°, and increasing it with the advancing temperature, avoiding cold currents, allowing an advance of 10° to 15° from sun heat, and closing early so as to husband it. It is best not to hurry the Vines in the early stages, but after coming into leaf they must have sufficient heat to secure steady development and progressive growth.

Increasing Rhubarb (*Learner*).—When the crowns are beginning to move is the best time to lift, split into pieces each with a crown or two and some roots attached, and replant. No crop better repays for liberal treatment at the roots. Where possible the ground should be broken up two or three spits deep and good manure mixed with each spit. The divisions may either be planted singly or in groups of three, arranging the stations 3 feet apart. Sink the divisions so as to bury all but the crown or buds, fixing them firmly. Mulch early with strawy manure, cut out any flower heads that may develop, and do not pull any leaves during the first season. Rhubarb is easily propagated from seed, but the plants do not all come true to name. The seed may be sown in March, thinly, in rows 15 to 18 inches apart, eventually moving alternate rows and half of the plants from the rest. A few weeks will be gained by sowing the seed at once in pans of light soil and placing it in gentle heat.

Rust on Carnations (*W. B.*).—Old rusted plants cannot be cured, they should be burned. Good results, however, have been obtained by removing the worst infested "grass" and then spraying the plants with dilute Bordeaux mixture, repeating at occasional intervals. The strength of the Bordeaux mixture may be 1 oz. each of copper sulphate and freshly burned lime to a gallon of water. Sulphide of potassium, 1 oz. to 10 gallons of water, has also been successfully applied, and some growers have got rid of the rust by the aid of permanganate of potassium, 1 oz. to 3 gallons of water. The application, in any case, should be made upon the first appearance of the disease, and repeated at intervals of about ten days. Of course, the thing is to prevent the disease, for which purpose we know of nothing better than dilute Bordeaux mixture, or dusting occasionally with the preparations of sulphate of copper in powder, such as anti-blight and fostite. Soluble phenyle has a burning effect on foliage, and can hardly be recommended. If it is tried begin with a strength of 1 fluid oz. to 6½ gallons of rain water.

Eucalyptus globulus in Tubs Failing (*Blackpool*).—The most likely cause of the failure is general defective conditions of growth. A cellar is not a proper place for the tubs, as the soil will be deprived of air to a great extent, and their need of water or otherwise cannot properly be attended to. The structure also is very unsuitable, "10 feet wooden walls with a rolled plate glass roof with two coats of white paint on the outside, no top ventilation, only end doors, and six rooms opening into the corridor." Besides, the plants have been in the tubs about eight years. No wonder they sicken and go off one after the other. We should consider the plants have done well to live so long under the trying circumstances, and that the collapse now taking place is due entirely to the adverse conditions. Possibly the soil has become sodden and sour, and the plants have thus died from loss of roots. Of course, they may have been overwatered, and the conditions brought about have resulted in the death of the plants. On these points we can offer no opinion. Why not procure young plants, and grow them in tubs in the house, where they could be properly attended to? The plants like abundance of sunlight and air, just the very things they are deprived of in your case. Surely white paint is not a suitable material for shading purposes, but it has no doubt been used to give the requisite coolness in the structure during the summer. Ventilation ought to be provided, and the paint removed from the glass, using "summer cloud" or such preparation as could easily be washed off, and the plants thus have modified light in summer and full in the winter.

Names of Fruits (*D. J. H.*).—1, Shrivelled beyond the possibility of recognition; 2, Wellington; 3, possibly Kedleston Pippin; 4, unknown and worthless, probably never had a recognised name; 5, not sure, resembles Dumelow's Seedling; 6, Yorkshire Beauty.

Names of Plants (*T. E. R.*).—Specimens packed as yours were seldom reach us sufficiently fresh for identification. 1, is possibly *Davallia canariensis*; 2, too small and withered to even permit of a suggestion being made. (*P. A.*).—1, *Cattleya Trianae*; 2, *Cypripedium insigne*; 3, *Adiantum cuneatum*, varietal form; 4, *Pteris cretica albolineata*. (*W. T. C.*).—*Zygopetalum Mackayi*.

A TREAT FOR DINNER.

We believe it was said of the good king Henri Quatre, the Huguenot monarch of France, that he had so much at heart the prosperity of his subjects, great and small, that he did all in his power to promote prosperity, and that he considered one sign of that prosperity was that every poor man in his dominions should be able to afford a fowl to improve the contents of his Sunday soup pot.

We do not know whether the English artisan will ever arrive at this comfortable consummation; but we fancy a good many of them would have no objection to such a savoury morsel, and we fail to see any reason why the fowl dinner for Sunday, or indeed any other day, should not be greatly on the increase.

Fowls have come to be considered, first, the rich man's delicacy, and, second, the sick man's diet. So far, so good; but when we consider the quantity of excellent food on a fine fowl we wonder that it is not more sought after as a substitute for the everlasting beef and

mutton. Most households contain children, many a fine percentage, and a fowl would prove such an excellent and easily digested food for the youthful stomach.

Consider for a moment the numberless ways and the different guises in which this bird might be presented at table. He goes far because he brings with him so many little extras, not costly in themselves, but forming such pleasant additions.

Be a bit of bacon really too fat for any other purpose it goes down beautifully with the lean white meat. Be a loaf never so stale what excellent bread sauce it will make with the addition of a tiny—very tiny—onion, a little milk, and seasoning! Or, again, the same bread, with a portion of the fat bacon and a handful of garden herbs, is converted into the most excellent of stuffings.

With the boiled fowl may be used many of the white vegetables, which add much to the tastiness of the dish. For a bird which has seen several summers nothing beats a pie. Kill him, hang him several days, gently stew, then deposit under a plain but light crust, not forgetting the bacon and plenty of potato.

But we did not mean to write cookery recipes; we were going to talk of table poultry, and we are, well, not far afield, but, at any rate, intruding on the domain of the "Missus." She will perhaps say she can tell us more of table poultry than we can ever hope to know. We suspect she can, but perhaps is bashful, and leaves the work to our poor male pen.

Poultry may be divided roughly into three classes:—

I.—Poultry for showing.

II.—Poultry for egg production.

III.—Poultry for table.

The three classes cannot, and must not be confounded.

Far be it from us to look slightly on the exhibition; the exhibitors show us the best possible types. We have to take these types and adapt them to our purpose.

For table poultry we must aim at (1) early maturity, (2) quality, (3) quantity. We want small bone, much meat, good meat, firm meat, and quickly grown meat.

A silk purse cannot be made of a sow's ear, neither can inferior poultry be made into first-class "dead meat." We must begin at the very beginning; do away with all mongrel sorts; in fact if we have a mixed lot of ordinary barndoor fowl it is well to make a clean sweep, we then know what we are doing. We get rid of all aged and unhealthy birds, all crooked breast, and all bad doers—i.e., those with a touch of liver or tuberculosis.

To really succeed our best plan is to take a pure Dorking hen and cross with an Indian Game cockerel of a year old. The Dorking is a large type of fowl with very plump breast; the Indian Game cock is all meat, and the cross produced is, we may say, a perfect type of what a good table bird should be. Some breeders will after this cross mate the pullets with a Dorking cock, but after that no more crossing is desirable.

The chicks when hatched (which they should be early), for choice in an incubator, must be kept well up to the mark by constant and judicious feeding, and by a genial warmth. Without warmth no little chickens can live. We saw an instance of this the other day, where some foster-mothered chickens died in a very short space of time as the heat of their habitation had, through some carelessness, been allowed to go down. Chickens are always glad to avail themselves of an outside run, and whenever there is a gleam of sunlight they are out enjoying and benefiting by it.

We have only seen "cramming," so cannot speak of it from a practical point of view, but we know we can get chickens (of the right sort) very fleshy with ordinary good feeding. There are many other birds, or rather breeds, recommended as suitable for table purposes, but the consensus of opinion is all in favour of the cross of which we have spoken—Dorking hen, Indian Game cockerel, each the best of its kind. We hear of Langshan-English Game, which is really capital, La Bresse, La Flèche, Houdan, and Faverolle. Of these French birds we know best the Houdan, but we consider it, though large, a trifle coarse and given to bone. On the other hand it is an

excellent egg-making machine; and therefore is somewhat of a favourite.

We close with a description of what a Dorking should be, taken from the writings of a noted breeder thereof:—"A Dorking must be large in frame, long, deep, and broad in body, or it cannot possibly carry a great quantity of flesh, and as breast meat is especially desirable, we must look for specimens with large wings, for the breast muscles are the motors which open and close the upper limbs."

WORK ON THE HOME FARM.

Thunder and lightning, wind and rain! Floods are out everywhere that floods are possible, and even dry lands are becoming saturated.

Farmers who are always on the look out to keep forward with their work are distinctly getting out of patience with the present state of things. As we are promised a visit from the blizzard, which has played such havoc in the States, there is a prospect that their patience may be still further tried. We are ploughing our light sandy field for spring corn; it is land so dry that it never sets, and it is turning over well. A moderate frost after ploughing would put it into excellent trim.

We have carted manure out until the roads, and especially the gateways, are almost impassable; however, the congestion in the yards has been relieved, and we can leave that alone for a time. The difficulty is to find work for the horses. We are carting Thorns about, and filling up gaps and holes wherever Thorns are of use. There are heaps of road scrapings and refuse to be put on the land, but the same objection holds good here, as in the case of manure leading. Dry high-land grass, however, will carry the carts without much damage, and if the District Council is doing even half its duty, the roads should at any rate be passable.

Perhaps we may hear the remark, "Why make work when none needs doing? Give the poor animals a rest." Well, that sounds plausible enough, but it is not easy to keep a horse both healthy and idle, unless he is turned out to grass, and it is absurd to think of turning a horse out for a day or two in February. It is difficult to get the corn taken off unless the master feeds them himself, and a horse on dry winter food, kicking, not his heels, but the stall partitions, soon has a tendency to develop ailments which, with work and exercise, he would be quite free from. No. Keep your horses regularly and steadily at work; do not push them too far, but remember that one rest day in the week is quite sufficient.

If records were kept on every farm of ailments amongst the horses, and the statistics connected therewith could be tabulated, it would probably be found that a large and undue proportion of illnesses occurred on Mondays.

OUR LETTER BOX.

Books on Cows (R. A. C.).—"Cattle: Breeds and Management," by W. Houseman, 3s. 6d., Vinton & Co., 9, New Bridge Street, Ludgate Circus, E.C., is the best, if reference to diseases be important, as it has a chapter on diseases by Prof. J. Wortley Axe. Apart from that branch of the subject "The Dairy," by James Long and J. C. Morton, same publishers, 2s. 6d., may be recommended as more useful. Both refer to the management and feeding of cows and calf rearing.

REMARKS.

12th.—Rain from 5 A.M. to 7 A.M., 1.30 to 2.30 P.M., and after 10 P.M.; gale all day; much bright sun in morning.
 13th.—Windy with occasional sun and slight showers; heavy rain at 6.50 P.M. and 10.30 P.M.
 14th.—Alternate spots of rain and faint sun in morning; fair afternoon; slight shower in evening.
 15th.—Fair with occasional sun, and halo in afternoon; spots of rain from 5 P.M., steady rain from 8.15 P.M.
 16th.—Heavy rain till 2 A.M.; fine sunny day.
 17th.—Fog early, clearing gradually; sunny from 11.30 A.M.
 18th.—Fog early; sunny from 11.30 A.M. to 3 P.M.; more or less fog after.
 Another warm week, but not so exceptionally so as the preceding week.—G. J. SYMONS.

A FEW SPECIALITIES.

Barr's Monstrous Long Pod Broad Bean.—The earliest, best flavoured, largest podded, and most productive. Per quart, 2/6.

Barr's Green Haricot Dwarf French Bean.—Of very delicate flavour, and unsurpassed as a Haricot Bean in Winter. Per quart, 2/6.

Barr's Best of All Autumn-cutting Cabbage.—Dwarf and compact, very early and of exceptionally fine cooking quality. Per packet, 6d.; per oz., 1/6.

Barr's Earliest French Short Horn Carrot.—A favourite for soups, and extremely early; the best variety to sow in frames. Per packet, 4d.; per oz., 1/6d.

Barr's "Pride of the Market" Cucumber.—A specially fine dark-green variety of handsome shape; a favourite in Covent Garden Market. Per packet, 1/6.

Barr's Long Keeper Onion.—A fine handsome Onion, and a very long keeper. Per packet, 6d.; per oz., 1/3.

Barr's "First of All" Radishes.—Scarlet or white, fine little, short-leaved, very early Radishes. Per oz., 6d.

Barr's Early Ruby Tomato.—Bright scarlet solid fruit of fine form; an abundant cropper; the best FIRST EARLY Tomato. Per packet, 1/6.

Barr's Thick-fleshed Tomato.—Surpasses all other varieties for depth of fruit, solidity of flesh, high quality, and heavy cropping. Per packet, 1/6.

BARR'S SEED GUIDE (Free) contains a full descriptive List of the best Vegetables and most beautiful Flowers, with many Practical Hints on Culture valuable to Gardeners, Amateurs, and Exhibitors.

CATALOGUES FREE.

JOHN PEED & SONS,
WEST NORWOOD, LONDON.

FOR SALE.—Eight large *FICUS ELASTICA*, from 4 to 6 feet high, good, healthy stuff. Price on application.—Apply to "G." *Journal of Horticulture* Office, 12, Mitre Court Chambers, Fleet Street, London, E.C.

J. C. STEVENS' HORTICULTURAL, J. SCIENTIFIC, and NATURAL HISTORY SALE ROOMS, 38, King Street, Covent Garden, London. Established 1769. Sales by Auction nearly every day. Catalogues on application or post free.

GARDEN NETTING, small mesh, keep out the smallest birds, oiled and dressed; will not rot if left out in all weathers. 105 yds. by 1 yd. wide, 3/-; by 2 yds. wide, 6/-; 105 yds. by 3 yds. wide, 9/-; and so on to any width; carriage paid on all orders over 5/-. As supplied to the Royal Gardens. Commoner Netting, 50 square yds. for 1/-. I do not require payment until you have received and approved of the Netting.—From **H. J. GASSON**, Garden Netting Works, Rye.

No. 975.—VOL. XXXVIII., THIRD SERIES.

VEITCH'S GENUINE SEEDS

VEITCH'S CALCEOLARIA.

A superb strain, remarkable for its free-flowering qualities and compact habit of growth.

PER PACKET, 2/6.

CALLA ELLIOTTIANA.

FIRST-CLASS CERTIFICATE, R.H.S.

The trumpet is of a rich pure yellow, with dark green leaves conspicuously and evenly marked, and spotted white.

PER PACKET, 2/6.

VEITCH'S CHOICE CYCLAMEN.

J. VEITCH & SONS, LTD., were Awarded a Special Certificate by the Royal Horticultural Society for superior quality.

See Coloured Plate in Seed Catalogue for 1899.

PER PACKET, 2/6.

For full description of the above and many other CHOICE NOVELTIES and SPECIALITIES, see SEED CATALOGUE, forwarded gratis and post free on application.

James Veitch & Sons Ltd.
Chelsea.

FOR SALE.—GERANIUM CUTTINGS.

RASPAIL IMPROVED, the best Geranium for the cut flower trade, 9d. per doz., 5/- per 100; special price per 1000. Free for cash with order.

A. L. CHALMERS, St. Peter in the Wood, Guernsey.

ONION, NE PLUS ULTRA.—The largest and handsomest for exhibition purposes. Bulbs weighing from 3 lb. to 3 lb. 12 ozs. Per packet, 2s. 6d. True stock, only direct from the Grower—**LEWIS DUNBAR**, Seedsman, Hemel Hempstead.

ASPARAGUS.—This delicious vegetable does not require half the expense usually incurred. For simple instructions see SEED LIST, free on application. Strong roots from 2/6 per 100.—**RICHARD SMITH & CO.**, Nurserymen and Seed Merchants, Worcester.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd.**, Leeds.

COTTAGE GARDENING; being an Essay to which the Royal Horticultural Society awarded Mr. W. EGERTON HUBBARD'S Prize, February 16th, 1870. By E. W. BADGER. Third Edition. Price 3d.; post free, 3d. *JOURNAL OF HORTICULTURE* OFFICE, 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

ALL WHO WISH GRAND RESULTS should use **THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE**. This valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, **WM. THOMSON and SONS, Ltd.**, Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—Mr. J. GEORGE, 14, Redgrave Road, Putney. Agent for Channel Islands—Mr. J. H. PARSONS, Market Place, Guernsey. Also **THOMSON'S SPECIAL CHRYSANTHEMUM MANURE**. 1/2 cwt. Carriage Paid to all Stations in Britain and Ireland.

VINES FOR PLANTING.

OPINIONS vary as to the best types of Vine or cane for planting, and what answers well in one case may fail in another position, and as nobody is better acquainted with this fact than myself, I do not intend to lay myself open to a charge of dogmatism in the matter. When it is a question of establishing Vines as cheaply and quickly as possible in an inside border, then I say give the preference to the smallest canes procurable, if these are well furnished with roots. What are known as "cut-backs" are the best for either pot culture or for planting, and they can, properly treated, be grown into strong fruiting rods the same season as planting. Early in March, or just when the few buds are bursting, they should be turned out of the pots, soaked in a bucket of water the better to uncoil the roots without damaging them, and be planted at once where they are to remain. The roots ought to be spread out evenly and thinly, and be surrounded with a little fine, good soil. If a temperature of 55° to 60° by night, with 10° increase on bright days, be maintained, these young Vines will soon develop shoots, and these continue growing steadily, but never rankly, till the time has arrived for topping them.

I have given the best kind of planting Vines, and will now describe what, according to my experience, are the worst. Most Grape growers ought to be aware that Vine cuttings inserted in the open ground will root readily, and if the position is favourable, a Vine several feet in length will result the same season. In the Channel Islands they adopt this system of raising Vines, and succeed in producing canes 6 feet in length. They are intended for planting purposes, and are offered at comparatively low prices to planters on this side of the water. Instead of proving cheap, they are "dear at a gift." In addition to the canes being soft and imperfectly ripened, they naturally start into growth much later than desirable, and this whether forced or not. They are worthless for leaving to a length of a few or several feet, and ought to be cut down to near the old wood or original cutting.

No. 2631.—VOL. C., OLD SERIES.

Nor am I believer in strong, even if well ripened, canes for planting in a border. Whether pruned severely or lightly the result is apt to be much the same. They may break evenly and grow rapidly, only to stop suddenly, from exhaustion of supplies of sap. Not till fresh roots have been formed, and the leaves have turned this new sap to good account, does top growth recommence. In the interval the wood has hardened, and good growth afterwards is doubtful, at least for that season.

What are sold by nurserymen as planting canes are much to be preferred to the larger fruiting canes sometimes secured under the impression that the rods resulting the same season will be so strong as to more than compensate for the additional outlay. Strong canes are desirable where they have to be brought through from an outside border, and perhaps have to be trained to a good height before they are clear of hot-water pipes and latticed staging—a very undesirable but all too common arrangement. Where possible I would have the whole of the stems, or from where Vines are usually fruited down to the ground, clothed with lateral growth, this assisting materially towards swelling the stems. In the case of those brought through from the outside, it is difficult to avoid having a length of bare stems, but the new growth should be originated from the lowest point that sunshine and light can reach.

Planting large balls of soil and roots intact is unwise. It is next to impossible to keep the old soil sufficiently moist without saturating the new soil surrounding it, and new roots do not thrive when they reach the latter. On the other hand, if the ball of old soil once becomes dry remoistening is a difficult matter, and a stunted top growth is the result. Greater liberties can be taken with Vines when they are recommencing top growth than at any other period of the year. At that stage large old rods may be moved a considerable distance with little or no soil about the roots, and yet, if properly replanted and not forced hard, will produce a crop of small but serviceable bunches.

The larger pot Vines may, therefore, safely have their roots uncoiled, spread out, and distributed among the soil in a border, taking care to surround them with some of the finest and best of the compost, and thus treated will take quickly to their fresh quarters. What promotes root action quickly is a mixture of equal parts of fine loam, good leaf soil, and "burnbake," and from this the roots may be trusted to spread out into the ordinary compost in due course.

There is yet another class of planting Vines to be discussed, and which by some growers are preferred to any others. If "eyes" or short cuttings of well ripened wood are inserted singly in small pots of loamy soil, say early in January, they soon root in a brisk heat. Before the small pots become crowded with roots a shift into 6-inch pots is necessary, and if kept in a light position and fairly brisk heat the Vines quickly attain to a height of 3 feet, when they ought to be planted. Naturally, these newly raised Vines succeed best when planted in an inside border which has had time to become warmed somewhat by the aid of direct sunshine and hot-water pipes; but I have known them make good progress when planted in an outside border, the soil of which was close to the front wall plate of the vinery. Early in May is a good time to plant these young Vines in an inside border, a month later answering better in the case of an outside border only being available.

Some of the grandest one-year-old canes I ever saw were grown by Mr. Roberts when at Gunnersbury. Some old Vines had been hard forced, and directly the crops were cut cleared out "bag and baggage." A narrow strip of new border was formed, and in this the young strong growing Vines were planted, if I remember rightly, early in June. By the autumn all had ripened perfectly, and a good house of Grapes, so I was subsequently informed, was obtained during the next season, and the loss of a single crop obviated.

Those who may adopt this plan of planting quite young Vines must not attempt uncoiling the roots, as this would cause a serious check to the top growth, and, maybe, make all the difference between failure and success. There is no necessity for it. They must be kept steadily moist at the roots, while the top growth should have the benefit of genial heat and a moist atmosphere.—W. IGGULDEN.

ANNUAL ASTERS.

ASTERS are popular flowers, because of their hardy and free-flowering habit of growth, as well as the brilliant show the plants usually make when in flower. The dwarf varieties, including the *Chrysanthemum* flowered, are very floriferous, and adapted for massing in beds. Truffaut's French *Pæony*-flowered is much taller. The flowers are extremely bright in colour and incurved. The Victoria Asters are also taller in growth, and have large brilliantly coloured flowers of various soft and delicate shades. The petals of these curve outwards. The variety Comet is exceedingly popular, especially the white, resembling as it does white Japanese *Chrysanthemums*. The quilled Asters are novel and peculiar, also the cockade or crown-flowered with white centres.

Asters are among the best of annuals, and easily raised from seed. No annual is more brilliant and showy during the time of flowering. Strong plants must be planted if good results are to be obtained, but fortunately this is not difficult if the right method of procedure is followed. I have always found it unnecessary to sow Asters before the middle of March, as good seeds germinate readily, and the seedlings grow rapidly under favourable conditions.

Small, shallow boxes, or 6-inch pots, are very convenient receptacles in which to sow the seeds. Efficiently drain the base with a few crocks and a layer of the rougher parts of compost, and fill up the remaining space with some light and sandy mixture. Leaf soil and old potting material is excellent for raising seedlings of Asters and other plants which do not require extra attention. Riddle the leaf soil, and mix well with the old potting material, which will probably be very dry. If so, it must be moistened sufficiently so that water will pass readily through, as after filling the pots or boxes, a watering should be given before sowing the seed. This usually obviates the necessity of applying water previous to the seed germinating. When the soil is sufficiently well drained, scatter the seeds on the surface, neither too liberally nor yet sparingly, Asters not suffering from moderate crowding in a seedling state if they do not remain too long, and are not weakened by heat. Cover the seeds with a layer of moist, fine soil and press down smoothly.

The pots or boxes may be placed in a greenhouse or in a close frame. They do not need strong heat, and are usually better without it, for seedlings raised hardily are much superior in every way. The process of germination goes on best when evaporation from the surface soil is prevented, which may be done by a covering of paper or paper and glass. When the seedlings appear admit light, and shortly elevate near to the glass in the structure so that they may have the benefit of the light. The next position for them must be airy. A frame is suitable where the lights can be opened and closed in accordance with the weather. Maintain the soil moist but not wet.

The next stage consists in pricking out the plants into boxes or in a cold frame a few inches apart, so that they may strengthen and assume a bushy habit by developing side shoots or exhibiting a tendency to do so. The soil in which the young plants are pricked out should be fairly good, consisting of loam, leaf soil, and decomposed manure. Into this the rooting will be freely made, and good fibres must produce the best plants. Four inches apart is a good distance to place the seedlings, an inch less if room is limited. The soil, whether in a frame or in boxes, may be placed over a layer of manure decomposed in character. Very little is necessary, as it is not desirable to encourage a rank growth.

Immediately after pricking out heavy watering is not required, but the plants may be sprinkled lightly in the afternoon and the lights closed. When pricked out in boxes it is assumed the latter are stood in frames until the seedlings are established. Give air freely on favourable occasions, and water as required. Full exposure must be given for some time previous to finally planting out.

Whole beds may be set apart for Asters, or borders can be occupied with the plants in masses. Liberal enrichment of the soil is helpful to the growth of the plants. Good decomposed manure or leaf soil incorporated with the soil when preparing the beds assists in retaining moisture in the soil as well as supplying food.

At the final planting lift the Asters with good balls of roots and soil attached, both being moist. Should the weather be dry at the time of planting the holes in which they are placed ought to be watered before inserting the plants. Then fill in the soil half way and water again, afterwards drawing the dry soil round the plants. They will then take no harm in the driest weather for some time. In borders with no obstructing plants a trench may be taken out, watered, and the plants placed in, soil filled in round them, again moistened, and finished with the dry soil.

The soil should be occasionally stirred about the plants so as to break the top crust and destroy weeds. In continued dry weather give water frequently, but the necessity for doing so often may to some extent be obviated by covering the soil with a light mulch of cocoa-nut fibre refuse.—S.

EPIDENDRUM WALLISI.

THERE are few more beautiful species in the genus than this, and perhaps its strongest claim to favour is the fact that for at least half the year, and generally more, the fine racemes of flowers are open, filling the house wherein it is grown with their delicate musk-like fragrance. Only recently, in visiting a neighbouring Orchid collection, I found this *Epidendrum* growing, not in the *Cattleya* house, as usual, but in a glazed corridor kept very little warmer than the *Odontoglossum* house in winter. Yet it looked well, and was flowering very freely, and while not exactly advising this treatment, I mention it to show how accommodating this beautiful species is.

I like to keep it in the *Cattleya* house, and where there are central as well as side stages, it should be on the former, so that the stems have plenty of head-room. Though usually seen some 2 or 3 feet high, these will grow as much as 6 feet, and when strong, produce the flower racemes not only from the apex, as is usual with this class, but also from the sides of the upper joints. The flowers are individually about 2 inches across, the sepals and petals straw yellow with more or less abundant crimson spots, while the lip is usually white or cream in ground colour, the crimson being disposed in flaky feathery lines. They vary a little in colouring, and if not spotted by damp, last upwards of five weeks in excellent condition.

During the time growth is most active it is advisable to keep a very moist atmosphere, and if it can be done conveniently without damaging other plants the stems should be lightly syringed at least once daily in bright weather; this will keep away thrips, these insects, if allowed to do so, soon disfiguring the foliage. The root moisture, too, must be ample, for at no period can the plants really be said to rest, while at times the demand on the roots is very great by reason of the rapidly advancing stems. Least of all is required, of course, during dull weather in winter, as it is then that evaporation goes on most slowly, and the plants are at their quietest time.

The roots are not difficult to manage. Like the tall growing section of *Dendrobium*—their old world compeers—they like a make-up of compost through which air and water filter rapidly, and nothing approaching stagnation need be feared. The pots should be fairly large and must be well drained, the crocks being covered with a thin layer of rough sphagnum moss. Equal parts of peat and moss, with a good sprinkling of rough nodules of charcoal or ballast, will make a good rooting medium, and the basis of the stems may be kept a little above the rim of the pot. Trim the surface neatly after securing the strongest growths to stakes, which will be necessary until the roots regain a hold on the compost. *E. Wallisi* is a native of New Grenada, introduced in 1874.

ORCHIDS ON BLOCKS.

While not recommending the use of blocks for Orchids in a general way, there is no doubt that some species at least like this method of treatment, and these, too, are kinds that are very difficult to grow in any other way. In a small collection of Orchids grown by an amateur not far from the breezy Newmarket Heath I recently noticed a very beautiful specimen of *Aganisia coerulea*, an Orchid that has worried many skilled cultivators more than most, yet here it was with no skilled attention beyond that of the owner, and growing away merrily.

Not that the use of blocks will always bring this peculiar Orchid into a healthy state, but there can be no doubt that the freedom enjoyed by the roots went a long way towards making it a success. The chief point to be remembered in this way of growing Orchids is that they are entirely dependent on the atmospheric moisture for their requirements, and no slackening of this must be allowed. Blocks may be of various kinds, but the most useful of all are made from stems of Tree Ferns cut into suitable lengths, according to the size and habit of the plant. Cork, apple, and teak blocks are all useful for various kinds, and I never had such a fine stock of imported *Dendrobiums* of the *Devonianum* class than some that were fastened to small rough blocks of apple wood, these in their turn being sunk in pans of clean crocks until the roots were sufficiently advanced to allow of the addition of a little compost.

The distinct and beautiful *Cœlogyne pandurata*, again, is another Orchid that does well on a long block. The pseudo-bulbs are distant from each other, and soon grow out of the ordinary pot or pan; but on a long piece of Tree Fern stem the rhizomes can lengthen and spread laterally, and will soon make a large and handsome plant. Many others could easily be named that like the block treatment, and surely

some of our Orchid growing readers have tried it, and could give instances of successful treatment or the reverse. Both would be interesting.

DENDROBIUM NOBILE WALLICHIANUM.

This is a grand form of the old species, and an excellent one for retarding so as to bring it in for spring shows. When showing in classes for stove and greenhouse ent blooms I could usually keep this back for the spring show at Bath, when it was a welcome one of twelve at that season. Its habit of flowering upon the last matured stems instead of those two years old is in its favour, especially when, as is often the case, flowers and fresh foliage are produced upon the same stems. The plant makes very long stems (pseudo-bulbs), and for this reason should—especially when flowering later—go at once into strong heat in order that the growth may be in time for ripening with the waning sun in autumn.

LELIA ANCEPS.

When this species has taken a brief rest after flowering there is generally a number of young roots that begin to push from the base of the old bulbs. Sometimes, indeed, they appear before the flowering season is really over, but whenever they are seen the plants should be gone through carefully, and any that need it repotted or top-dressed. As a general rule it is treated to too much compost, for though the roots are strong individually they do not care to push through a great thickness of material, preferring rather to ramble about over the face of a rough block or a few lumps of ballast or charcoal.

Baskets and trellised rafts often take the place of pots for this reason, the amount of air that filters through these being of great assistance to the roots. Regarding the details of culture required for this lovely plant they have been frequently given in the *Journal of Horticulture*, so we will merely say keep it in a light, fairly cool house, hardly shaded even in summer, water the roots well, and keep the plants clean. This will insure a magnificent winter display, and when the varieties are good few plants are more beautiful. Take Mr. Crawshaw's lovely variety of *L. anceps* *Amesiana*, and few will fall out with you for calling it a thing of beauty, while among those less rare and valuable there is a large number of splendid garden Orchids that will always be popular.

COLAX JUGOSUS.

Those cultivators who only like large showy flowered Orchids will probably care little for this, but it is an interesting and pretty species well worth growing by those who like such. Imported many years ago by the then famous nursery firm of Hackney, Messrs. Loddidge, the treatment at that time thought necessary for Orchids was not at all to its taste, and in all probability it was lost to cultivation for a time. If not absolutely extinct it was extremely rare, and until more rational methods came in vogue it was likely to remain so.

Heat to Orchids of this class should always be moderate and tempered by abundance of atmospheric moisture. If dry and hot conditions prevail the plants will be overrun with thrips in a very short time. Even a dozen years ago *C. jugosus* was rarely seen in the condition our best growers exhibit it nowadays, and in place of the pretty green soft-looking foliage, this was covered with black lines formed by insects. Improved methods of fumigating have helped towards this desirable end, as well as a better atmosphere. The flowers occur on three-flowered scapes, and are individually about 3 inches across; the sepals and petals white, the latter prettily marked with violet purple. The lip is three-lobed, the front one deep violet, the side lobes lighter; a very pretty combination of colour.—H. R. R.

CHARCOAL FOR ORCHIDS.

IN response to the note (page 103), in which I am asked why I discontinued the use of charcoal, I now propose giving my ideas. I am well aware that good Orchids have been grown by its aid. But do we take the trouble to find the reason why we do a great many things in connection with gardening? You rightly say it cannot do harm if of the right quality; but does it do any good? When it is not of proper quality, I think it distinctly does harm, as I have found, when potting plants which have been in the same pot or pan for four or five years, the charcoal quite rotten, and resembling a piece of black chalk, and every root that was near it dead. I have found live roots clinging to charcoal where it has been exposed to the atmosphere on the surface of a pan, or at the bottom of a basket, and therefore I consider where it is used, it should be so placed.

Charcoal, if used at all for Orchids, should be made from Oak, and even then, from the sappy portions of the wood it is not of very long duration. The heart of the wood is the portion that should be used, and this is very rarely to be obtained. The lightness of it may sometimes be a disadvantage when a plant is at rest and its roots have not a thorough hold, as when water is required the plant is apt to be, when dipped, floated out of the receptacle. I trust other growers will give their ideas respecting this interesting question, as the more we investigate these matters, the better it is for gardeners and gardens, as it is on these small matters which a great many of our hopes are shattered.

In place of charcoal I use pieces of soft porous bricks, which can generally be obtained anywhere, broken into different sizes, and used according to the size of the pans or pots used. These do not decay, and the roots seem to revel on them, and they keep the compost sweet and porous. I think when the compost gets into a solid mass, as is mentioned in the note, it is usually to be attributed to faulty watering. Of course the compost will naturally decay, but if the plants are doing satisfactorily I have always found that they are ready for a shift by the time the compost is sour.—J. T. B., *Hessle*.

EUPHARIS CULTURE.

IN moving from one situation to another a young man will find at times distinct methods pursued in the treatment of the same plant, and having in my journeyings seen several successful ways of growing *Eucharis*, a few notes culled from memory may be acceptable to readers of the *Journal of Horticulture*. No plants in our hothouses afford more pleasure than a collection of well-grown *Eucharis amazonica* (grandiflora), free from the dreaded mite, and kept clear of that great enemy mealy bug.

Living in the north of London some years ago, I first made the acquaintance of a large number of these plants; I had had to deal with them before, but only on a comparatively small scale. To begin with the treatment. In November the plants were cleaned of all pests, and plunged in a hotbed at the end of a Pine stove. Here year by year they flowered at the end of December. How proud we youngsters were of them, and indeed they made a beautiful display with their leathery leek-green leaves, and splendid flowers rising above them in the dead of winter. After a few weeks we were rewarded by a second crop of blooms as good as the first. About the end of April the plants, as a rule, flowered again, but neither the spikes nor the individual flowers were so good at this period. Manure water and soot were given during the weeks of forcing, alternately with clear water, the old safe rule of weak and often being followed. Of course a brisk temperature was found necessary, and as far as possible provided, from 65° to 75° being aimed at. Syringing was practised on the foliage on fine sunny days, abundance of moisture in the growing season appearing to meet all requirements.

In May they were moved into a cool stove to rest and in a measure recuperate, and from about the middle of August until forcing time again they were relegated to a corridor connecting two ranges of vineries. Labour was none too plentiful in that establishment, but the *Eucharis* had to be kept clean, and so now and again a solution of paraffin and rain water (a wineglassful to 3 gallons of water) was mixed in a large tub; one man was told off with a syringe to keep the mixture in motion, and another to dip the plants as they were brought out, and wash with clear water before being taken back to their places. It was surprising how quickly the plants were cleansed in this manner.

I never knew the veterans to be potted; some younger plants, however, which were being grown into large specimens, were transferred each year to larger pots, with a compost consisting of three parts loam, one of leaf mould, a small addition of decayed manure, and a dash each of sand and soot. Where these plants were placed in the autumn the old-fashioned sliding roof-lights were always down full length, for the purpose of ripening the wood of the Peaches on the back wall, the front sashes being also open night and day. I have seen the leaves white with morning dew, quite as near hoar frost as it ought to have been. The plants, however, showed no sign of injury, though the foliage lost some of its vigorous colour, but this soon returned when the plants were again in a higher temperature and being generously fed. Watering, of course, was a matter which required great care; at the time of cool treatment very little was necessary, and that only at long intervals.

After a year or two it was my good fortune to have charge of a houseful of these beautiful plants. Here we had plenty of labour, and to keep the foliage free from mealy bug the sponge was requisitioned. In October the temperature of the house in which the *Eucharis* were growing was lowered about 10° for a few weeks yearly. With this exception the culture was practically the same all the year round, a rather high temperature with a corresponding amount of moisture in the atmosphere being given. It was seldom we were unable to cut two or three dozen blooms, even when they could scarcely be said to be in season.

Unless a pot happened to get broken, or, as not infrequently occurred, the pots were burst by the roots, revealing the great white bulbs, I never saw one of these plants potted. I believe for eight or ten years no general repotting took place, yet the plants looked in the pink of health, and certainly I have seen none since to flower better or so continuously. With the few weeks' exception of rest previously mentioned feeding was carried on throughout the year, liquid manure being given once a week and a very slight dusting of "Thomson's" at lengthy intervals.—J. SHALFORD.

NOTES ON CINERARIAS.

FEW plants are better adapted for conservatory decoration during February and March than *Cinerarias*. When a good strain has been grown they provide an endless variety of beautiful shades of colour which give pleasant surprises daily to flower lovers. Hybridists have long devoted special attention to them, and their efforts have been splendidly rewarded; there seems, indeed, to be no limit to the beautiful shades of colour which are being continually produced, if we except a yellow form, which is never likely to be raised, seeing that blues and yellows never occur in the same species of florists' flowers. It seems scarcely possible to produce plants of a better habit of growth, or individual flowers of larger size and finer substance, though there is undoubtedly room for improvement in the form of some of the large flowers, they lacking the perfectly circular shape, with the edges of the petals overlapping in a way that delights the eye of an expert florist. True, we have many flowers quite perfect in this respect, but the giants, as a rule, have a weakness in that direction. This, however, is a matter which will probably be overcome in course of time.

Cinerarias are as easy to grow as most plants when the right system is pursued, but few things will go wrong sooner if in the least neglected. It is no uncommon occurrence to see a grand collection of plants at the time they are housed in the autumn: but when the flowering period arrives, the same set of plants often look disappointing by reason of the edges of the leaves having become browned, and in other ways disfigured. This is generally more noticeable among plants grown in small pots than in larger specimens; why this is so I will attempt to explain. Two things will cause disfigurement of the leaves—viz., mistakes in watering and overcrowding. The seed for plants intended to be flowered in 5 and 6-inch pots is often sown too early, with the result that by the time autumn arrives the soil is so packed with roots that unremitting attention is required to keep them from going wrong. As long as the plants remain in cool pits where they can be given abundance of air and room, they thrive well; but by the time November arrives, it is seldom safe to leave them longer in unheated pits, so they are transferred to a cool house, and then the disfigurement begins, not because the house is an unsuitable one, but from mistakes in watering.

At this stage, although the soil is packed with roots, it is an easy matter to overwater, because very little growth is going on, and the days are often dull and cold; it is just that season of the year when a good waterer begins to change his tactics, preferring rather to err in the matter of under than overwatering. Yet some waterers, knowing that the plants are so abundantly rooted, fear to let them get slightly dry, and habitually give water a little too soon. The result is that many of the young white roots are killed, and the plant shows the check experienced by a slight rust at the edges of the leaves, and when this once comes it cannot be obliterated, but will often quickly spread. Now let us look at the other side of the matter.

In trying to avoid overwatering the plants are sometimes allowed to get too dry. A dull foggy morning is perhaps followed by an hour's bright sunshine, and plants which are dry at the roots would perhaps take little harm if the day were dull throughout, but the sunshine causes them to flag, and if not attended to quickly, roots in this case are also killed. But the after result is shown in a different way. The leaves become flabby and flag whenever the weather is bright, ultimately some of the bottom ones die and leave a leggy plant. The watering of *Cinerarias* is an art, which requires to be performed at the right time; neither too soon nor too late.

In the watering of plants in large pots more care is usually exercised, as the waterer is aware how quickly a fine specimen may be ruined by overwatering, consequently sufficient time is taken to thoroughly test each pot, whereas when dealing with a number of small plants the work has to be done quickly. There is this point, too, in favour of the large plants—viz., that as they are usually placed in their flowering pots early in the autumn their roots are active throughout the winter, yet as they have plenty of soil to work among they do not suffer to any great extent if sometimes allowed to become too dry; and as the space left for holding water is generally ample, a sufficient quantity can be given to thoroughly moisten the whole of the soil. These may appear small matters, but they are important enough to contribute largely toward success or failure.

Now for a few words about arranging the plants in their winter quarters. I like to place each on an inverted pot, as I find the extra trouble is well repaid; for although *Cinerarias* delight in an atmosphere uniformly moist, they do not like moisture lying upon the leaves during cold damp weather, and by raising the plants on pots the necessary moisture can be distributed on the stage without wetting the leaves, which if done is a fruitful source of another kind of leaf disfigurement—viz., damp. When *Cinerarias* are grown in light houses some means of shading ought to be in readiness by the beginning of March, or the leaves will flag badly during bright weather.

Fumigating should be practised occasionally even when no traces of green fly are visible, for when once it obtains a sure footing both the health and beauty of the plants are quickly marred. Feeding with liquid manures, both natural and chemical, should be regularly practised, always giving such in a greatly diluted form.

The beginning of March is soon enough to sow seeds for producing large plants in 9 and 10-inch pots, and the end of May for those intended for flowering in 5 and 6-inch ones.—H. D.

HYBRID POTATOES—REPORTING PROGRESS.

In your issue of March 17th, 1898, page 244, I gave you particulars as to how we planted out my "Jubilee" hybrid Potatoes in 1897. Their features were carefully noted, and the selected tubers from them I had planted out last mid-May. Their physiognomies became again watched, and the foliage kept peppered with the anti-blight powder. Thirty of them, early and second early, were selected, and taken up in the order of precociousness, and their characteristics for form, flesh, and colour noted down. I have retained seven of them as early and six second early varieties. None of the other seventeen—which proved very late rank growers, throwing enormous bunches of berries, and thus proving for me stamina, but the paucity and appearance of the tubers, to a practised eye, show them to be not worth keeping, and for that matter I do not care to introduce any more late sorts. I have, however, in every likelihood secured what I want with this Fendleri cross in early and second earlies: yet they do not even now bear sufficiently close "at home." In Dame Nature's good time I could correct this wandering tendency, and I find also to dispose of a disagreeable lingering flavour, always found in wildlings more or less, and also gain a little further increase in size for universal garden household purposes, albeit Mrs. Fenn says the representatives—allowing of course for the camera curtailments shown in the plate—are quite large enough for her. Nevertheless you will allow them to be a "triumphant" march over those two diminutives for which you bespoke a "report progress" on page 3, January 5th, 1893. I propose for myself in the future to persevere only in this way with wildlings from new latitudes, as I consider the acme of perfection for the esculent is arrived at; that I cannot work any further improvement by intercrossing with the original species or the American strains accruing from those of Virginia, Peru, or the Andes.

So now for my last comer, "*Solanum bulbo-castanum*, Duval (Guadalupe Old Mexico)," sent to me by my old corresponding American friend, Mr. Pringle. It is no new thing, "friendship with Americans," with me; *esto perpetua* with us all! You can quote more about the introduction of this new species, if you think necessary, from Mr. Pringle's letter on page 244, March 17th, 1897. Suffice it for me to show the growing appearance and the uplifted crop—save the mark, "crop"—by photographs, through a kind medium, Mr. Anderson, the same ingenuous youth who "took" the Chrysanthemums. You will perceive the foliage to be unlike any of our present edible varieties. Last year it gave its blooms from a tuber, the only one liliputian I could preserve. In the former season it blossomed from the seed sent to me, but up to the present it refuses to become cross-fertilised with my domesticated varieties; nevertheless, with the twenty-four years' tussle that I have undergone with the Fendleri from New Mexico, I do not intend to despair of conquering castanum from the other side of the Gulf of North America—viz., if I can maintain a fulcrum to arrive at an evolution of that inexorable law, the "survival of the fittest."

I fear, though, the investigations of a hybridiser will gain him little credit in connection with the esculent, if I may judge by the papers in these columns, since my last record in your issue of March 17th, 1898. Be this as it may, it will not prevent my customary anxiety to give you, before I "go under," my particular experiments, which must necessarily at first prove "small Potatoes, and few in a hill," and will certainly not meet the ideas of those large-minded growers who say they, or somebody else, can produce so many pounds from a single tuber, or an amazing plurality of tons per acre, thus hailing Nemesis to quickly fill their sacks and overstock the markets with inferior coarse produce, which—if it is to be judged of as a paragon of perfection to go by—will soon render for the growers very little profit indeed because of the over-abundance.

However, that may end, within the last twenty years or so, Potato raisers, by crossing, have followed in such yearnings for size as to offer a fair prospect of spoiling the esculent for all purposes excepting the idea of filling their breeches pockets, or for prize money. Relative to flowers, to work for size and admiration in competition can do no harm, but where is the benefit for the million to come in by creating bloated watery Potatoes—for is not the human system composed of three-quarters water already—and then to cross with these again to produce larger swollen obesities? A few years ago, as I was assorting some seedlings in the bay of my barn—one variety of them approached to the size of a child's head—our squire, Major Thoyts, happened to

call upon me about some parish business, and expressed his astonishment at the size of the one mentioned above, adding, "I suppose those are for the Messrs. Sutton's?" "No; they are to be boiled for the pigs—exterminated—as 'delusions and snares.' We do not want these monsters continued further than they have gone."

Agriculturists have gained a march upon us here by the extinguishing of the mountainous cattle for their shows, with which they erst used to "astonish the natives." It is high time the British public should be more considered in this way in regard to their vegetable food, in Potatoes more especially, for they take their place next only to Wheat. But we all know, or at least we read, how the last and most advertised are, according to the catalogues, the best. Notwithstanding, let me, if you can allow space, say somewhat about my own productions, which I have tried to keep to the fore, in regard only for substantial subsistence. They are the Rubens, Rembrandts, and Vandyks, analogously as being the original outcomes, handed down by long perseverance in cross-fertilising from the best blood, so to speak, of our good old English var., not to be procured now for love or money; and these, again becoming cross-pollen-fertilised from the choicest American sorts, produced for me the best Potatoes in the

FIG. 32.—A CHARACTERISTIC PICTURE FROM MR. FENN.

world. Those which we have succeeding them are after-interbred-cross copies, and do not surpass their progenitors for support or flavour; giants and colossuses, I grant.

Well, I never had a better yield from my Potatoes than last season, from off the same ground too where I have cultivated—excepting a few samples of recent raising—them from the consecutive seeds for twenty-three years; not that I disapprove of a change of soil or seed, just the contrary. Again, it would be impossible for me to obtain a transfer of tubers in their integrity of my out-of-commerce sorts; in fact, I never for my own seed let it out of my hands. You may be inquired of, "How do I manage, then, to cultivate so successfully, following on the same ground?" Answer: Analogous to Beau Brummel and his "cravats." Trenching and deep cultivation "is the man." I never care about expensive artificial manures; farmyard manure, soot and salt, burnt debris, old mortar, ashes, and earth closet soil as I can procure them are sufficient for me.—ROBT. FENN.

[We reproduce (fig. 32) the veteran's original Pea-like tubers from his S. Fendleri ×, with the progress up to date as represented in the tubers on the plate; also the inverted Seakale pot in which he grew them, the fork with which he dug them, and the bellows with which he blew the disease away by his favourite anti-blight. The writer, as he recently stated, has "just struck eighty-four." With the view to future improvements it will be noted he is going to start *de novo* with the "wildlings." We hope he may pass into history as the Potato centenarian.]

RECENT WEATHER IN LONDON.—Frosts have come daily of late, and have been comparatively severe. On Saturday, Sunday, and Monday mornings the white frost was accompanied by fog, which happily cleared later in the day. On each day there were gleams of bright warm sunshine, though the light wind was cold. Tuesday was foggy, but Wednesday opened clear and bright.

— WEATHER IN THE NORTH.—Cold winds from the east have been prevalent during the week, and generally the weather has been seasonable; sunshine fairly effective in tempering almost continuous frost. This has varied from 3° to 9°. A dense fog set in on Sunday evening; on Monday morning the hoar frost was intense, and 7° frost were recorded. The day was marked by hazy sunshine.—B. D., *S. Perthshire*.

— SHREWSBURY HORTICULTURAL SOCIETY.—The Honorary Secretaries of this excellent Society have favoured us with a copy of the report and balance-sheet for the year 1898. From a perusal of the former it is easy to gather that the executive body is thoroughly satisfied with the progress that has been made. This is only natural considering that after disbursing nearly £4000 there remains as the balance of assets upwards of £470. This must be most gratifying to everyone concerned, and to none more than Messrs. Adnitt & Naunton, who as Honorary Secretaries are indefatigable in their endeavours to maintain the standard that has been attained since the inception of the Society.

— MR. G. HARRIS.—As announced in the *Journal of Horticulture* two or three weeks ago, Mr. Harris was preparing to commence business on his own account when he was offered and accepted the appointment of Horticultural Instructor for the counties of Cumberland and Northumberland. For the last seventeen years Mr. Harris has been head gardener at Alnwick Castle, and during that time he has given ample proof of his ability as an able and an excellent gardener. Like all enthusiastic gardeners, Mr. Harris has been at all times not only willing but anxious to impart his knowledge to others, and by his unflinching courtesy and kindness has won for himself many friends and admirers. The garden staff to the number of thirty, wishful to show their appreciation of their chief, presented him with a beautiful, mounted aneroid barometer. Mr. Stewart, head foreman, most appropriately made the presentation. Mr. Harris was much touched, and feelingly responded, thanking them all for their great kindness.

— SHIRLEY GARDENERS' ASSOCIATION.—The monthly meeting of the above Society was held on the 20th inst. at the Parish Room, Shirley, Southampton. There was a good attendance. The lecture was under the auspices of the Technical Education Committee of the Southampton County Council, and was given by Mr. E. T. Mellor, B.Sc., London, Lecturer in Biology at the Hartley College, Southampton, the subject being "The Influence of Light on Plants," and was illustrated by experiments and lantern slides. Several questions were put and answered, and at the close a cordial vote of thanks was proposed by the President and unanimously accorded to Mr. Mellor. There was a good display of spring blooming plants by the members, and Mr. H. Curtis, gardener to the President, was awarded first prize for three vegetables, that being the only exhibit in the class.

— FRUIT CULTIVATION BY FARMERS.—At the Farmers' Club, Salisbury Square, Fleet Street, E.C., on Monday, February 27th, Mr. Spencer Pickering, F.R.S., gave a paper on this subject, which attracted a large gathering of members. All the principal points in relation to fruit-growing on farms were dealt with, and especial stress was laid upon the fact that more attention was needed than had hitherto been accorded from an agriculturist's point of view. Examples of the gross neglect so apparent in many districts were described and the remedies indicated. The extension of fruit culture by an arrangement between landlord and tenant was advocated, and the method which found favour with the lecturer was one by which the landlord provided the trees and the tenant incurred the expense of preparation, planting, and culture. A system of compensation was also recommended, the actual amount payable to an outgoing tenant being determined by valuation. A vote of thanks to the lecturer concluded the proceedings, after considerable discussion had taken place on the various aspects of the subject.

— NITRATE OF SODA.—A paragraph from "American Gardening" recently stated that "the amount of nitrate of soda to be employed to the square metre (39 square inches) is about 30 grammes," &c. Obviously there is a little mistake here, as the area of a square metre is 10·7 square feet, or over 1540 square inches.

— GARDENING APPOINTMENTS.—Mr. G. Gregory, late of Kingston Lacy Gardens, Wimborne, has taken charge of the gardens of Hazelgrove House, Sparkford, Somerset, for the Rev. A. St. John Mildmay. Mr. Maurice Jones, late head gardener to W. Cooper, Esq., Cockley Cley Hall, Swaffham, Norfolk, has been appointed in a similar capacity to H. Michell, Esq., Undermount, Bonchurch, Isle of Wight.

— DIVIDING LOBELIAS.—With a number of stock plants in a healthy condition they may be pulled in pieces, each with roots attached, and put an inch or two apart in boxes of light soil. Place in a brisk temperature, and syringe daily until established. These when well advanced in growth may be again divided if more plants are wanted. They soon become established in heat and moisture.—E.

— ORCHARDS.—At the meeting of the Bedfordshire Chamber of Agriculture on February 25th, a paper was read on the above subject by Mr. L. Castle, manager of the Woburn Experimental Fruit Farm, to a large gathering of members. The different methods of planting were reviewed at length; the general management of established orchards was also referred to in detail. An interesting discussion followed, in the course of which Mr. Crick, of Ampthill, remarked that his experience of forty years as a fruit grower coincided exactly with that set out in the paper, and he stated that he was so well satisfied with results that he was about to extend his plantation considerably. Several other members took part in the proceedings, and related their experiences, which had not, however, in every case been so satisfactory as Mr. Crick's. A hearty vote of thanks was accorded to Mr. Castle at the conclusion of the discussion.

— THE ROYAL GARDENERS' ORPHAN FUND.—At a meeting of the Executive Committee, held on February 24th, Mr. William Marshall was unanimously elected Chairman for the ensuing year. The following special receipts were announced, and the contributors heartily thanked:—Mr. Matthew Todd, Maitland Street, Edinburgh, £33; Mr. H. J. Jones, Ryecroft Nursery, Lewisham, S.E., £15 4s. 6d.; proceeds of a concert organised by the Chislehurst Gardeners' Improvement Association, per Mr. J. Lyne, £17 10s.; J. Colebrook, Esq., Lowndes Square, S.W., £10 10s.; W. Roupell, Esq., Roupell Park, S.W., £5 5s.; Leeds Paxton Society, £3 5s.; Messrs. J. Moss and Son, Kelvedon, £1 1s.; Messrs. W. Thomson & Sons, Ltd, Clovenfords (collecting box), £2 12s. 3d.; Anderton's Hotel (collecting box), 10s.; Mr. Wm. Howe, Park Hill Gardens, Streatham, S.W., £1; and Mr. William Whittaker, Bridgwater, 10s. An intimation having been received of the death, prior to the annual meeting, of one of the orphans on the elected list, the Committee unanimously resolved to place Arthur George Wood, the next highest unsuccessful candidate at the late election, on the Funds as from February 17th. It is specially requested that all communications relating to the business of the Fund may now be addressed to the Secretary, Mr. B. Wynne, 8, Dane's Inn, Strand, London, W.C.

— HESSLE GARDENERS' SOCIETY.—A meeting of the above Society was held on Tuesday, February 21st, when Mr. F. Mason presided. Mr. J. P. Leadbetter, gardener to A. Wilson, Esq., Tranby Croft, read an instructive and valuable paper on Potatoes, their culture and variety. The essayist first dealt with the history, then with the advancement made in the mode of culture, describing how at the present time more Potatoes were produced from a decreased acreage than formerly. He dealt with the diseases the plant is subject to, also describing various remedies, and finally giving the varieties he found best to answer his own requirements. The usual votes of thanks brought a pleasant evening to a close. The sixth annual dinner of the above Society was held on Thursday, the 23rd inst. W. J. Wharwick, Esq., presided, and was supported by all the officers and about sixty members and their friends. The loyal and other toasts were duly proposed and responded to, and, amid much enthusiasm, "Our Journal" was responded to by Mr. Donoghue of Tranby Croft. By the generosity of the President the famous Kingston Quartette party was present, and interspersed the toasts with various vocal items, Mr. Thompson, who provided the comic clement, coming in for a large share of applause. Kindred societies were represented by Messrs. Winns and Schofield of Grimsby. Everything passed off quite satisfactorily, and a highly enjoyable evening was spent.—J. T. B., *Hessle*.

METEOROLOGICAL OBSERVATIONS AT CHISWICK.

No rain has fallen since the 15th; the temperature has been steadily going down, and the wind has varied between N.E. and S.E. Fog has been prevalent, being very dense on the 24th and 25th.

— FRAGRANT FREESIAS.—It will be remembered by many readers that in our issue of January 5th, page 12, were some practical notes from Mr. G. Carpenter, West Hall, Byfleet, on Freesias and their culture. As illustrative of the suitability of his methods of procedure, Mr. Carpenter now sends examples of flowers and foliage, than which for substance and richness of fragrance no one need wish better, and it is all too seldom we see them equally as good.

— PETUNIAS.—Now that seed stocks give of double varieties such wonderfully fine flowers, it is a matter for surprise that these plants are not more generally seen as pot plants both in the conservatory and at exhibitions; not only have the flowers high class form, but generally the petals are pleasingly fringed, and the colours are charming. I was recently looking over a large collection of plants of Sutton & Sons' strain, and the grower said that from seed 50 per cent. at least came finely double. That is a good return for the small cost of a packet of seed, especially when it is remembered that all the best can be easily propagated by the aid of cuttings, and be thus perpetuated. Plants from autumn rooted cuttings grown in 7-inch pots, and occasionally pinched to make them bushy, develop into fine plants, and make for a long season a beautiful display, and are most attractive as exhibition specimens.—A.

— CAMELLIA ROSEIFLORA.—The beauty and usefulness of Camellia japonica and its varieties as garden plants is probably responsible for the fact that other species are more or less overlooked. Some of these, though of no use for cut flowers, are worth a place among greenhouse plants, as they flower well in a small state, and make a change among ordinary plants at this time of year. The plant under notice is a Chinese species, with glossy green ovate leaves $2\frac{1}{2}$ inches long by an inch across. The flowers are borne several together in great profusion, plants 2 feet high often bearing from fifty to 100 or more blossoms. They are rosy pink in colour, semi-double, and about 1 inch across. It flowers annually in the temperate house at Kew, where it is much admired. A figure of it is given in the "Botanical Magazine," t. 5044. Being of easy cultivation there is no reason why this plant should not be added to the collections of people who are fond of variety among greenhouse or conservatory plants.—W. D.

— RAISING CANNAS FROM SEEDS.—I thought just at this time when many, no doubt, are purposing to use Cannas for bedding a hint as to raising them might be of use to some readers. It is often suggested soaking them for, say, twenty-four hours. On March the 1st of last year I put some seeds in a bottle and stood them on hot-water pipes in a vinery, and occasionally removed those that were comparatively soft, placing them in small pots. I tested them on the flagstones by holding them about 6 inches from the floor and letting them drop. If they were still hard I put them back in the water. The others remained until April 20th, when I became impatient, and took out all and cut off the hard outside on one side of the seeds sufficient to see a small white speck. Then they were put in pans in brisk bottom heat, all being through the soil in from five to ten days of the date of sowing. I raised about 100 last year in this manner, and flowered them in four months from the time of soaking. This is the second season I have adopted the plan with success.—R. BARFOOT, Mayfield Gardens.

— LIVERPOOL HORTICULTURAL ASSOCIATION.—Mr. H. Sadler writes:—"I have been requested by the Committee of the above Association to draw your attention to the report of our annual meeting which appeared in a recent number of your paper, in which it was stated that the balance in hand at the close of the year amounted to £80. I enclose you account showing that this is an error, the amount being £120." We gladly make this correction.

— RECORD CYCLAMEN.—Noticing "Wanderer's" remarks (page 145) on Mr. W. James's fine collection of Cyclamen at Farnham Royal, I thought perhaps your readers would be interested in what I believe the finest Cyclamen plants ever exhibited. They were shown at the Brighton horticulturists' monthly meeting, February 16th, by Mr. C. Murrell of Franklands, Burgess Hill, and were awarded the first prize and the Society's certificate. The plants in question carried about 150 finely developed flowers each, and measured just over 2 feet across. What about silly Sussex?—A. G. D.

— TREES FOR CITY STREETS.—Of all trees those which are found to do best in the murky atmospheres of great cities are the Planes. The reason of this is that the Planes possess the characteristic of peeling off their outside bark at regular intervals, so that they are continually presenting fresh surfaces, as it were, to the destructive agencies playing upon them. The great cause of the failure of trees in cities is the clogging of the little openings on their surfaces with particles of soot and other deleterious substances found floating in such smoky atmospheres. The saturation of the soil with coal gas and other noxious compounds is also a fruitful cause of failure.—("Irish Farmers' Gazette.")

— READING GARDENERS' ASSOCIATION.—By the aid of limelight views, and under the guidance of Mr. C. H. Curtis (an old Kewite), a large number of members of the above Association spent a pleasant evening at the club room of the Old Abbey Restaurant in inspecting the houses and grounds of Kew Gardens. Before separating the President of the Association, C. B. Stevens, Esq., proposed a vote of thanks to Mr. Curtis for coming to Reading and giving the members an insight to Kew Gardens without having to go to Kew, and referred to the interesting way in which the ramble had been conducted, showing that their guide had a thorough grasp of the subject and an excellent acquaintance with the ins and outs of this noted educational establishment.

— HISTORY OF THE LONDON PARKS.—It is announced that a work of great interest to Londoners, written by Colonel Sexby, will be published in a few months by Mr. Stock. The book is a history of the London parks, gardens, and other open spaces under the supervision of the County Council, or otherwise available for public recreation. It will be a striking record of municipal progress in a humane direction. But besides this, the history of many of these parks and gardens forms an attractive chapter in the general history of political, social, literary, and artistic London. Colonel Sexby will tell us about the famous personages and events associated with the London parks and gardens, and the once famous buildings that stood near or upon them. The author's duties in the London County Council have made him familiar with all details of his subject. The work will contain a very large number of illustrations and plans from old and modern sources.

— THE SOIL.—What a change in the condition of the ground and its working has been wrought in a week under the influence of dry sunny days, with north-easterly winds, and white frosts at night. At the moment of writing, after a week of such weather, the soil is in splendid condition for working, for sowing and planting. How rapidly the evidences of rain have disappeared, and with the dust flying in our streets and roads as though it were March, it is so difficult to realise that but a few days ago and all seemed in danger of being flooded with overflowings consequent upon the heavy rains. Anyone who assumed that we were having too much rain can hardly think so now—indeed, many rather desire that we may have many falls ere the summer is with us. But the dry weather, in thus permitting time for the water to get away and the soil to become so admirably workable, has done much to stimulate labour in gardens, and whether early or not very many, especially where the soil is naturally porous, are sowing, besides Peas and Beans, Parsnips, Onions, Carrots, and other seeds, the state of the soil and the weather proving to be so tempting. Whether in doing so thus early they are wise subsequent weather will show. It does not do to jump to the conclusion that the winter is gone. We have yet to face the treacherous month of March, and we may have through it some severe weather. If it keeps dry, and the temperature is but moderately low, we shall have much to gain in keeping things in check. Already there seems to be on the part of trees and bushes too much premature movement that is not welcome to the gardener.—OBSERVER.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—FEBRUARY 28TH.

As might naturally have been expected, the meeting at the Drill Hall on Tuesday was a very small one. The heavy fogs and sharp frosts of the preceding days would materially prejudice the exhibits. Those staged were of an interesting character, and of excellent quality.

FRUIT COMMITTEE.—Present: George Bunyard, Esq. (in the chair); with the Rev. W. Wilks, and Messrs. J. Willard, J. Smith, F. Q. Lane, Geo. Wythes, S. Mortimer, P. C. M. Veitch, A. H. Pearson, E. Shaw Baker, W. Poupert, Jas. Veitch, Jos. Cheal, Robert Fife, and A. Dean.

Mr. H. T. Martin, Stoneleigh Abbey Gardens, Kenilworth, exhibited a dish of Apple Rouen. Messrs. R. Veitch & Son, Exeter, sent a dish of Mannington Pearmain in good condition from the original tree, also roots of Sandwich Island Salsafy. Mr. R. C. Notcutt, Broughton Road Nursery, Ipswich, sent two dishes of stewing Pear Winter Orange in very fine condition.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); and Messrs. Geo. Paul, R. Dean, Wm. Howe, J. Hudson, J. F. McLeod, J. Jennings, C. T. Druery, C. J. Salter, T. Peed, H. Selfe-Leonard, W. Bain, J. D. Pawle, C. R. Fielder, J. Walker, C. E. Shea, E. T. Cook, H. J. Cutbush, Harry Turner, J. Fraser, J. W. Barr, and E. H. Jenkins.

Messrs. Wm. Paul & Son, Waltham Cross, staged a very handsome collection of flowering shrubs, comprising good specimens of Forsythia suspensa, capital plants of Prunus triloba beautifully flowered, the double Almond, the Carnation-flowered Peach with bright rosy red flowers, the Camellia-flowered Peach, and a number of foliage plants, such as Euonymus, Golden Privet, and Aralia Sieboldi (silver-gilt Banksian medal). Mr. F. Miller, 110, Fulham Road, contributed a bright display of Cinerarias of a dwarf type, also a floral display of various devices composed of spring flowers (silver Banksian medal).

Mr. Purnell-Purnell, Woodlands, Streatham Hill, staged a large collection of Narcissi and Cinerarias. The former were well represented by N. rugilobus, N. poeticus, N. Leedsi, Purity, Emperor, Empress, and Horsefieldi. The Cinerarias were dwarf and sturdy, but the plants were barely ready (silver Flora medal). Messrs. Paul & Son, Cheshunt, contributed an interesting collection of Hellebores and white Lilacs. The former included Helleborus colchicus coccineus, H. Willie Schmidt, H. roseus superbus, H. caucasicus punctatus, and H. orientalis; also a number of other spring flowering plants.

The St George's Nursery Company, Hanwell, contributed a grand display of Cyclamens in a great variety of colours. The plants were remarkably well grown and covered with bloom (silver gilt Banksian medal). Messrs. Sander & Co., St. Albans, exhibited a large plant of Acalypha Sanderi and a number of A. Godseffiana, also a fine specimen of Hippeastrum procerum with pale blue flowers. Mr. John Russell, Richmond Nurseries, Richmond, exhibited baskets of Laurustinus albus; the plants were well flowered and pure in colour—also baskets of Hedera arborea fructo-lutea and Skimmia Fortunei well berried.

Mr. T. S. Ware, Ltd., Tottenham, exhibited a very pleasing display of spring flowers. The Daffodils were excellent, and comprised N. bicolor Victoria, Emperor, Sir Watkin, Leedsi, Horsefieldi, and Burbidgei, pots of Iris reticulata, Fritillaria oranensis, blue Primroses, and hardy Cyclamens. Messrs. J. Veitch & Sons, Ltd., exhibited plants of Amygdalus persica magnifica. The flowers are a bright rosy red, and formed a very attractive exhibit; also plants of Primula floribunda. Lady Margaret Boscawen, Tregyne, Cornwall, contributed some very fine bunches of Neapolitan and Marie Louise Violets, the colour being perfect and the flowers a good size. Messrs. Barr & Sons, King Street, Covent Garden, staged excellent Daffodils, N. Victoria, Golden Spur, incomparabilis, Beauty, Captain Nelson, and a number of minimus; also Lachenalias Nelsoni and pendula. The quaint Iris tuberosa, hardy Cyclamens, and a few Primulas and Cinerarias were also sent.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); and Messrs. J. O'Brien, de Barri Crawshay, J. Colman, N. Cockson, H. Little, A. Outram, H. J. Chapman, F. J. Thorne, W. Thompson, E. Hill, F. Mason, H. Ballantine, J. Douglas, T. B. Haywood, T. W. Bond, and H. T. Pitt.

Mr. F. Knight, Thundersley Hall, Thundersley, Essex, contributed a small group of Lælia superbiens, Odontoglossum Rossi majus, Brassavola glauca, and Cattleya Trianae (bronze Banksian medal). Messrs. H. Low and Co., Bush Hill Park, exhibited a collection of well-grown Orchids carrying flowers of good form and rich colour. Varieties of Cattleya Trianae were conspicuous, as were Cyrtopodium Sanderæ, C. Boxall atrata, C. i. Dormani, Dendrobium Wardianum, D. Findleyanum, D. Phalenopsis, Lælia harpophylla, Odontoglossum crispum, O. Andersonianum, and others (silver Banksian medal). Mr. A. Kitwell, gardener to D. M. Grimsdale, Esq., Uxbridge, showed Cyrtopodium villosum aureum and Mastersianum, with Odontoglossums luteo-purpureum sceptrum, triumphans, and maculatum. J. Rutherford, Esq., Blackburn, staged a good form of Cattleya Trianae named Rutherfordiana.

G. Thompson, Esq., Stamford Hill, showed Dendrobium nobile var., while Mr. F. J. Thorne, gardener to Major Joiey, Sunningdale, sent Dendrobium atro-violaceum and Lycaste Lingwilia. De Barri Crawshay, Esq., Sevenoaks, exhibited Odontoglossum Ruckerianum Crawshayanum, O. Andersonianum Bogardiana, and O. Rossi Crawshayanum. Sir William Marriott, Bt., Blandford, showed Sophro-Lælia Marriottiana; and Mons. Jules Hye, Ghent, sent Odontoglossum Franz Mazerell. Messrs. J. Veitch & Sons, Chelsea, were represented by Phalenopsis Ariadne, Hebe, and F. L. Ames. Mons. C. Maron, Brunoy, France, sent

Lælia Cattleya callistoglossa J. Leemann, Cyrtopodium tonkinense, and Lælia-Cattleya Ernesti Princess Olga.

From Mr. J. Edwards, gardener to G. S. Clark, Esq., Wrexham, came Odontoglossum Rossi majus rubescens, O. crispum Mrs. Stanley Clark, and a hybrid Cyrtopodium. Mr. W. Stevens, gardener to W. Thompson, Esq., Stone, Staffs, showed Odontoglossums Wilckeanum concinnum, O. excellens spectabile, O. coradenia expansum, O. crispum Daphne, and O. c. Dorothy (silver Banksian medal). Messrs. W. Shaw and W. Gould, Stockport, showed one or two plants each.

CERTIFICATES AND AWARDS OF MERIT.

Cyrtopodium Surprise Hybrid Albino (Jules Hye).—This is pale green with a yellow suffusion in the pouch. The dorsal sepal is grass green with a broad pure white band (award of merit).

Lælia-Cattleya Ernesti Princess Olga (C. Maron).—A superb flower. The colour is of the brightest canary yellow except the centre of the lip and throat, which is crimson (first-class certificate).

Lælia-Cattleya callistoglossa J. Leemann (C. Maron).—This is in all respects an advance on the type (first class certificate).

Odontoglossum Ruckerianum Crawshayanum (de Barri Crawshay).—A distinct form. The sepals are rosy purple with chocolate patches, and of similar colour in the petals, but with spots instead of patches. The lip is creamy white with a large chocolate red central patch (award of merit).

Odontoglossum Cookeanum (H. Ballantine).—A striking though small flower. The prevailing colour yellow, barred and spotted with chocolate brown (award of merit).

Odontoglossum Vuylstekianum, The Dell var. (H. Ballantine).—This is a lemon yellow beautifully fringed form of the type. The sepals and petals have large spots (award of merit).

Prunus persica vulgaris alba flore plena (W. Paul & Son).—This is a fine variety with pure white semi-double flowers (first-class certificate).

Rhododendron Exquisite (J. Veitch & Sons).—A lovely variety, with pure yellow flowers and bright red stamens (award of merit).

Rhododendron Hercules (J. Veitch & Sons).—A handsome form, with flowers of an orange buff colour. There are occasionally six and seven segments (award of merit).

HEREFORDSHIRE FRUIT GROWERS'

ASSOCIATION.

A WELL attended and influential meeting of fruit growers and farmers was held at Hereford on Wednesday, 22nd February, for the purpose of starting a Fruit Growers' Association for Herefordshire. The Mayor of Hereford presided, supported by Sir James Rankin, M.P., Mr. C. W. Radcliffe Cooke, M.P., Mr. J. Riley, and Mr. Beddoe.

Sir James Rankin, M.P., proposed that an association be formed, and that it be called "The Herefordshire Association of Fruit Growers and Horticulturists." He considered the county of Hereford had much to recommend it for fruit growing, and that unless the members of the Society combined in earnest no amount of talk would avail. Small fruits, he was sorry to see, had decreased in cultivation. He alluded to the work of the Technical Instruction Committee, of which he was the Chairman, and said the Secretary would do all he could to promote the objects of the Association. Cottagers should be encouraged to grow fruit. A tenant of his had made £20 a year profit from three-quarters of an acre of land. Foreign competition must not be lost sight of.

Mr. J. Riley seconded the resolution. He alluded to some of his failures in fruit culture during the past twenty years, and remarked that, if an association similar to what he understood it was proposed to start, had been in existence twenty years back, failures and much needless expense might have been saved him. The railway companies had the power to make or mar the English fruit trade, and an association of several hundred members stood a far better chance of treating with a railway than an individual did. The resolution was then put and carried.

Mr. Radcliffe Cooke, M.P., then proposed the comprehensive resolution of the various objects of the Association. After enumerating same, he proceeded to say he was quite in favour of such associations, as for years past he had endeavoured to persuade the Government to encourage and assist fruit culture, and, if possible, to follow the example of the Canadian Government, who had five experimental fruit farms; these were of great benefit to those who wished to start fruit growing. Whenever he had made the suggestion he was met with the retort that it was not a matter for the Government, that it must first be taken up through the energy and enterprise of the people themselves. They were now in Herefordshire going to give a practical illustration of that doctrine—they were going to take the initiative themselves. Mr. Long had told him that if an experimental farm were started for, say, the counties of Gloucester, Worcester, and Hereford there was no doubt the Government would give a grant. The farmers and growers must, however, make a beginning themselves. He alluded to the immense area that used to be under fruit in Herefordshire in the seventeenth century.

Mr. Beddoe seconded the resolution, which was then put and carried.

The Mayor then proposed, seconded by Mr. Allen, that Sir James Rankin, M.P., be asked to become President of the Association, which resolution was agreed to with applause.

After this a Committee was proposed and agreed to. At the conclusion of the meeting over fifty of those present became members of the Society.

SEASONABLE HINTS ON FLORIST FLOWERS.

WHAT an extraordinary season this is through which we are now passing—somewhat similar, indeed, to last year, but more favourable in its character with regard to gardeners, inasmuch as we have had in this south-eastern part of England a fair supply of that rain of which we were so deficient in the early part of last year. Of frost and snow we have had none, never more than 3 or 4 degrees of the former and only a few flakes of the latter. Some of our days have been more like spring than winter, and now that we have passed more than half through the month of February we begin to think that the winter is gone. We may have a rude awakening yet; but now already our borders are gay with Crocuses, Scillas, Aconite, hardy Cyclamens, Anemones, and Snowdrops, and how delightful to us all these early flowers are; but what effect has this strange season had upon our florist flowers?

Take, for example, the Auricula. I do not see that they are one bit more forward than in ordinary seasons, nor have the winter and autumn trusses been more abundant than usual. Some sorts there are which are always inclined to commit this mistake, and whether the season be early or backward makes little matter to them. We have had no trouble about covering up our frames or pits, and it is too early yet to determine whether the flowering season is likely to be an early or a late one. As far as my judgment goes, the culture of the Auricula for exhibition purposes does not seem to increase very much; the flower is not a popular one, although those who are really interested in its culture are devoted to it. At the present time the great object of the grower is to see that his plants are clean—that is, free from green fly, and none of them water-logged. If any of them have been unfortunate enough to have been under a drip they ought to be examined at once; it may possibly be that a worm has got in and disarranged the drainage; this can be ascertained by turning the pot up upon the hand, and if the intruder be found he will have little mercy shown to him.

Of late years the desire for decorative plants has led to what are called fancy varieties being more cultivated. These are showy, free flowering, and many of them very bizarre in character; but of course they do not find favour with the old florists, who like myself were brought up in a very strict school, where any departure from the established rules of criticism was resented. One would advise growers now to get in any new sorts, but as far as florists' varieties are concerned these are very few, for you cannot propagate the Auricula as you do many things—you must depend upon its power of giving offsets, and in many cases these are very sparingly produced. The character of the weather at the present time is most favourable for giving them air on all occasions, taking care, however, that they are preserved from rain.

CARNATIONS AND PICOTEEES.

The season has also been most favourable for these, and I have no doubt that those who grow them in the open during the winter have found it to be so; but as I grow but few I never venture to expose them, but keep them in pots during the winter, and in looking at mine now I find them in the most healthy condition, no spot or appearance of fly, but with good green healthy foliage. This is another flower in which there has been a vast change of taste. This has arisen from two causes; the overdressing of the old florist varieties made it very disappointing for anyone who saw a stand of beautiful flowers arranged, and then tried to grow them, to find out that unless he possessed the art of dressing them he had no chance whatever of equalling the flowers he had seen; and here again the wish to have more decorative flowers in greater quantity made a great revolution in public taste. This was greatly encouraged by the wonderful success that attended the earnest labours of Mr. Martin Smith in producing what may be really called a new race; from his seed we have flowers of the most varied hues, good form, large size, and great fragrance. He distributed these seeds liberally to members of the National Carnation and Picotee Society, so that in all parts of the country we see the results of his efforts. As border plants they are invaluable, producing large quantities of good flowers, and so making a great effect. There is now no longer need of carefully watching over a plant or two, which, after all, might refuse to grow; we can get plenty of foliage and strong layers. As the days advance the plants will require more water until the time for planting out, but it had better not be overdone, and air should be given on all possible occasions. Towards the end of the month I take my plants from the pits or frames and place them out of doors under a shelter where they are protected from wind and rain but have air upon all sides. This hardens them, so they are in a better condition to plant out by-and-by.

GLADIOLI.

The beds ought now to be carefully forked over when the weather is fine to get ready for planting, though it is too soon for that yet. When large quantities are grown the small corms and seedlings should

now be planted, but the larger ones must be kept in safe position until April. I notice that the corms of the Lemoinei group are very strong, and do certainly seem to be hardier than those of the gandavensis section, although neither have yet made their appearance above ground.

PANSIES.

I suppose that in the South of England we must confine our attention to growing these plants in pots; our hot and dry summers make sad havoc with them when planted out of doors, they become infested with mildew and the plants perish altogether. I therefore of late years have never grown them except in pots. It is advisable now to stir up the soil with a blunt stick and tie the long straggling shoots to almost invisible stakes, for the beauty of the blooms is greatly marred when the shoots hang about in all directions. Here again a great change has taken place. The show varieties, as they used to be called, are very seldom met with; the Fancy or Belgian varieties, as they are called, though mostly mixed in this country now, have entirely superseded them, and yet when the late Mr. Charles Turner wrote his little treatise on the Pansy Fancy varieties did not exist. It is to the Scotch growers—Laing, Downie, Laird, Paul, Dobbie, and others—that we are indebted for the large and showy varieties which we now possess. To see them in perfection you must see them growing in Scotland or in the North of England.

RANUNCULUSES.

No flower, I think, has suffered by the change of fashion more than the Persian Ranunculus, yet what could be more beautiful than a bed of these exquisitely formed and most varied flowers, ranging through almost all shades, except perhaps blue? I remember the time when a single tuber was catalogued at half a guinea, and yet as far as I know these are nowhere to be had now; the Dutch florists still keep up a large collection, but I cannot find amongst them those varieties that used to please one in earlier days. You get much larger flowers, but they very soon show the eye, and then all their beauty is gone. I have managed to get enough roots to plant a large bed, which I hope to do in the course of a few days. They should be planted about $1\frac{1}{4}$ inch under the ground, the rows 5 inches, and the roots to be placed 4 inches apart in the rows. All worms should be, if possible, taken out of the bed, for they have a very unpleasant practice of getting under the tubers and throwing them out of the ground. After the bed is planted it must be very gently smoothed down, but not with the rake. There is a class which is called French varieties, but they lack the perfect form and symmetry of the older kinds.—D., Deal.

PYRETHRUMS.

WHAT wonderful strides have been made of late years in these useful hardy herbaceous perennials, and no small meed of praise is due to those painstaking hybridists. Messrs. Kelway & Son of Langport, for the most beautiful varieties that from time to time make their appearance. The uses to which Pyrethrums may be put are almost innumerable, but certainly dotted about in clumps in the border they look charming, and with a little judicious attention regarding varieties, we have a blaze of colour when the larger herbaceous flowers are somewhat scarce.

From the middle of May to the beginning of July they are greatly in evidence, and with good cultivation the yield of bloom is enormous; and being able to be cut with long stems, the variety of floral work to which they may be adapted is almost endless, and one would like to see them grown in greater profusion.

Regarding their successful culture, there are few plants that require so little to bring about a good return, as even in the commonest of soils a profusion of flowers is the result. But it is when sound loam and well-decayed manure are thoroughly mixed, and supplies of liquid manure given during the growing season, that the quality of flower and robust appearance are manifested. Timely attention to staking is also essential, as, although the blooms seem scarcely to suffer from the rain, yet if allowed to touch the soil they soon get damaged. The requirements to insure a second crop of flowers in the autumn is after flowering to cut down the old stems and to remove a little of the surface soil, replacing by new material, making all firm. If the weather is dry give heavy supplies of water. The new growths will soon make their appearance, and it is from them that a watering with liquid manure twice a week will work wonders in the size and profusion of the flowers obtained.

The season of planting may be said to extend over a very long period, but the present cannot well be improved upon, and an early purchase will insure happy results. Where so many seedlings abounding in beautiful colours can be purchased at a moderate cost I will not attempt to speak of the selected named sorts which are catalogued, and which ought to find a place in all large establishments. Suffice it to say that purchasers may have the choice of either double or single varieties, and I should strongly recommend both, in colours varied from the choicest selfs to almost every conceivable intermediate shade. The single varieties are charming for house decoration, the yellow eye noticeable all through being a fine set off against the coloured petals.—R. P. R.

VIOLAS, NEW AND OLD.

PERHAPS at no period in its history has the Viola of our gardens been so popular and widely grown as at the present time, and this popularity, fortunately, is not confined to gentlemen's gardeners, but is spread amongst amateur gardeners in all parts of Britain. This love of the Viola has encouraged specialists to raise and distribute every year enormous quantities of new varieties; nearly every grower has a new sort which has (in his eyes) some outstanding quality better than his neighbour. This is all very well if he keeps his gems at home, but if all that are offered were sold at 2s. 6d. each to all other lovers of the flower, it would mean bankruptcy to some of them. With the view of affording beginners some reliable information on new and old varieties, I went through an extensive collection when the plants were in bloom and noted those most suitable for showing, bedding, and affording flowers for cutting.

SUPERIOR NEW VIOLAS.

Blue Border.—Dwarf, sturdy habit; free-flowering; purple edge, white centre; good for show or bedding purposes.

White Hart.—Not a pure white, has a slatey tint through it; is a first-rate bedder.

Lord Malcolm.—A purple self, very strong yet sturdy grower; splendid for showing in sprays, but not free-flowering.

Romeo.—Not of robust habit, but is a delightful flower; purple striped with white and pink; a novel colour.

Jeannie P. Robertson.—White margined with lavender; a chaste flower, rather tall grower; a beauty for exhibiting.

Juliet.—Grand foliage, very strong grower, purple and white, like the old and well-known Countess of Kintore, but much better; excellent for show or bedding.

Alida.—White edged with mauve; a very compact growing variety, free flowering, and the flowers have the merit of having long stems, therefore are suitable for table decoration.

GOOD OLDER VARIETIES.

Duchess of Fife, primrose edged with blue, is still one of the best, especially for exhibition. Duchess of York is a fine white. George Lord, primrose and rayless, is suitable for any purpose. So is Flower of Day, cream colour.

J. B. Riding, a deep mauve, has a fine habit, and is first-class for show or bedding. Hamish, crimson and purple, is fine for showing, the flowers being large. Hamlet is one of the most novel colours I know, rich crimson and scarlet flaked with purple and pink, large flowers; a splendid show flower. Iona is another fine flower, either for show or bedding; first-class habit, free flowering; the colour is blue-black and lavender.

Prince of Orange, very deep yellow, is a capital bedder. Princess Louise, pale yellow, excellent habit. Pembroke is rather tall, but the flower is very fine indeed. Norah May is a pale lavender; a large, chaste, and beautiful flower, useful for any purpose.

Princess of Wales, a rayless yellow self, forms very compact tufts. Sylvia is a rayless primrose flower and fine bedder. Mrs. C. F. Gordon, lavender blue, a good show flower or bedder. Stobhill Gem is very similar. Princess Ida, rosy heliotrope, is fine for show or bedding. Mozambique is similar to Mrs. Gordon but not so good. Marchioness, a fine creamy white self, is a prolific bloomer, and one of the best for bedding. Rosa Pallida, a dwarf grower, pale lavender, is very effective in line and beds.

Mrs. J. Donnelly is a real bedding Viola, being of flat growth and extremely floriferous. White Duchess, a light sport from Duchess of Fife, is very chaste. Royalty is a fine bedding yellow, so is the dwarf growing large-leaved Lord Elcho, which, though old, is very good and reliable. Jessie Prestwell, white striped with rose and purple, is a lovely show flower. Archie Grant, a large blue flower, with fine foliage, is still one of the best of all bedders.

A. J. Rowberry is one of the finest yellow Violas yet raised—a smooth rayless flower, good for any purpose. Cecilia, creamy white edged with pink, is a splendid show flower. Dandie Dinmont, purple, is good for exhibition only. Florizel, bluish lilac, fine free growth; a beautiful variety. Edina, dark blue with white markings, fine for bedding or show. Devonshire Cream is an excellent show flower; and Favourite a grand bedder of good habit. Mrs. Charles Turner is a first-rate bedding blue; so also is True Blue, raised by the late Mr. Wm. Dean, who always maintained it was the best bedding blue Viola grown—and it is one of them.

Of the sweet-scented tufted Violettas there are many varieties, none however surpassing the original creamy white, "Violetta." This makes a delightful edging to any bed, and should be left undisturbed for some years. Gold Crest, deep golden yellow, and Oliver, a blue self, are also good; so is Picotee, a striped variety.

To succeed with Violas they must be well cultivated. They are not particular as to soil; but it should be deeply dug, and have a generous admixture of good well decayed manure. One very essential

point, too, is to plant early, especially in the South of England; late planting is simply courting failure. As soon as the ground is in any thing like good condition the plants should be put in, say, the second week in March, and in May, if at all possible, they ought to have a mulching of some sort. If Violas can be left for two or three seasons undisturbed and well looked after, glorious displays are the result; not show flowers perhaps, but, better than that, plenty of show in the garden.—VIOLA.

FLOWERING PLANTS FROM SEED.

MANY useful plants for cutting and decoration may be readily grown from seeds. At the present period of the year nearly all seed which is sown should be sown in pans or boxes which can be placed in heat, as by this means germination is more quickly insured, and the seedlings make considerable headway in time for transplantation into other boxes or a slightly heated frame where they are able to become strengthened prior to being planted out finally.

Marguerite Carnations quickly germinate now. Sow on the surface of light soil placed in boxes or pots, and cover the seed lightly with fine soil.

Lobelias for bedding are easily grown from seed. Wide, shallow pans are the best. Give ample drainage, and fill with a mixture of light loam and leaf soil, making the surface fine and smooth. Distribute the seeds as evenly as possible, and dredge a mere covering of soil or fine sand over them through a sieve. Place in a little bottom heat and cover with glass and paper. The seeds soon germinate, but great care must be taken with the seedlings to prevent their being spoiled with too dry heat or excessive sunlight.

Campanula pyramidalis can be raised without heat, but it is an advantage to sow the seeds at once in pots of moist soil and place in gentle heat. After germination expose to light in a cool house and transplant the seedlings early, later on potting them singly. These plants do not flower the first season, but it is a distinct gain to enable them to have a long season of growth, with several repottings, so that the plants may be strong for flowering finely the next season.

Pentstemons may now be produced from seed, and the plants resulting will, with good and liberal treatment, flower the same season. Fill a wide seed pan or shallow box with good loam and leaf soil in a moist condition. Make firm and level, and sow the seeds thinly, just covering with fine soil. Cover with glass to prevent evaporation. A slight bottom heat will be enough to give the seeds a start, and when the seedlings have appeared above the soil raise the receptacle close to the glass in a warm house. When large enough to transplant give them more room in other boxes, from which they may be finally planted in a position for flowering.

Antirrhinums when raised early appreciate a little heat, but after germination has well commenced give a cooler position. Any light open mixture will suffice, making it fine on the surface, as the seeds are very small. Merely dust over them a light covering of soil or sand. Prick out the seedlings an inch or two apart in boxes or a frame, so that they may enlarge and strengthen for the final planting. The dwarf varieties should be sown and grown separately from the tall.

Verbenas are bedding plants which can be grown from seeds as well as from cuttings. Place some good light soil in boxes and sow the seeds thinly on the surface, which should be moistened previously. Cover the seeds with a thin layer of soil. When the seedlings have attained sufficient size prick them off into boxes or pot singly.

Primroses and Polyanthus make fine plants if seed is sown in pots and the seedlings pricked out in a cold frame in May, watering freely in dry weather.

Ten-week Stocks require sowing a little earlier than Asters, and ought to be sown thinly so that each seedling may have a chance of growing sturdily. There will then be less mortality among them, Stocks being very subject to damping off if the seedlings are crowded.—E. D. S.

PRIMULAS AT WORDSLEY.

THE Primula of to-day bears little resemblance to its prototype of the sinensis family of sixty years ago, and scarcely any of the florists' flowers have been improved with such rapidity. The weak, puny flower of that period, elevated on attenuated flower stalks, has developed into flowers borne in trusses, splendid in size and substance, rising from bold stout foliage. With the most careful hybridisation, followed by the same care in selection, we appear to have arrived at the time when the Primula as a winter and spring embellisher of greenhouses and conservatories must always remain the flower *par excellence*. With the advance above noted Messrs. Webb & Sons have kept abreast of the times. One of the firm's finest productions is named Purity, and amongst the several houses full of fine varieties, Purity stands forth as one of the most charming. The plants are vigorous and full of health. The dark red bronzy foliage, borne on stout footstalks, is surmounted by the pure white flowers,

each having a disc of pale sulphur. The trusses are carried well above the foliage, and the effect of a house of plants in full bloom is most striking. Continuing with the light coloured forms, it will be equally true to say that the position enjoyed by Purity in the whites is followed closely, if not surpassed, in the tinted varieties by Modesty, which magnificent variety opens white, but when fully expanded gradually deepens into a pleasing and delicate pink or flesh colour. The habit of the plant is superb, dwarf, sturdy, with Fern-leaf foliage of a beautiful green. The crimped flowers are of great size and substance, and are produced in profusion on stout stems. It is an exquisite variety, which visitors are not slow in appreciating. The flowers keep well, and for this reason should prove invaluable for table decoration.

Another rosy tinted variety finds an appropriate name in Rosy Morn. It is of the plain-leaved section, with somewhat deeper coloured flowers than the preceding. This elegantly fimbriated Primula must become popular. The colour is novel, carmine rose, deepening several shades

ducing spikes continuously, and these lengthen into whorls of flowers, until the plant assumes a pyramidal shape. To those seeking a unique colour Eclipse will appeal very strongly, for whether grown in quantity as at Wordsley, or singly, the purplish crimson flower is sure to gain attention and admiration. Careful selection and the weeding out of rogues assiduously persisted in, has brought a Primula worthy of the name it bears. The yellow disc in the centre is well defined, and the bold flowers are heavily fringed, which render the variety very useful and quite indispensable where shades of crimson are favoured. The growth is dwarf and compact, and with the dark red foliage below and gaily trusses of flowers above, is a variety of which everyone must make note.

Of the blues, Webbs' new Blue Belle is no washed-out apology, or a pale blue even, but a blue pure and simple. I remember the first blue Primula, and can thoroughly appreciate the progress that is now manifested. At Wordsley it is true, and in good character. The plants are dwarf with dull red stems and dark leaves, and flowers of a decided blue,

FIG. 33.—PRIMULAS AT WORDSLEY.

here and there on the same flower with age. It is somewhat taller than Modesty, but is equally as free-flowering. Although there are several other of the lighter coloured section all of merit, space will not permit more than a reference to the leading varieties at present.

Let us then pass on to colour, such as is rarely seen in the Primula family, with especial reference to Firefly. I doubt if the insect of that name ever shone so brightly as its counterpart in nomenclature. It strikes one as a glorified type of the Old Chiswick Red, a Primula hard to approach, much less to surpass, ten years ago. The colour is vivid dazzling crimson, dark-stemmed, with the bloom resting, as it were, on crumpled foliage. The effect of a large collection of this variety on a dull January day is most pleasing, and everyone who desires to add cheerfulness and colour to their conservatories must perforce grow this acquisition in bulk.

Scarlet Emperor too, calls for attention. In colour it is what I should designate soft scarlet. The chief point in this splendid variety is the wealth of bloom the plants carry. And yet there is size as well, and it makes one wonder that bad socks are tolerated by anyone when plants like Scarlet Emperor can be grown without any more trouble and expense. This, too, has dark foliage similar to Purity. It is strong and vigorous, with flower stalks carried well above the leaves, and keeps pro-

ducing spikes continuously, and these lengthen into whorls of flowers, until the plant assumes a pyramidal shape. To those seeking a unique colour Eclipse will appeal very strongly, for whether grown in quantity as at Wordsley, or singly, the purplish crimson flower is sure to gain attention and admiration. Careful selection and the weeding out of rogues assiduously persisted in, has brought a Primula worthy of the name it bears. The yellow disc in the centre is well defined, and the bold flowers are heavily fringed, which render the variety very useful and quite indispensable where shades of crimson are favoured. The growth is dwarf and compact, and with the dark red foliage below and gaily trusses of flowers above, is a variety of which everyone must make note.

In conclusion, Messrs. Webb & Sons, with increased facilities for the reproduction of the grand strains, may go on, as indeed they are at the present time, selecting and hybridising. Practical in all their dealings, the partners place only the best before their customers, who are the supreme judges of quality, and in these days of keen competition this must be the keynote of success.—G. M. A.

[We can corroborate our correspondent's remarks on the Wordsley Primulas. We know the grower, Mr. W. Dyke, to be a close observer, who is always ready to increase his large store of practical knowledge from any available source. The illustration (fig. 33), from a photograph supplied by Messrs. Webb & Sons, represents a house of Primula Purity, about whose merits, with the above notes and such a picture, nothing more need be said.]

ROSE PESTS.

ROSES in houses which are being brought on steadily by the aid of a little fire heat have been making rapid progress during the last few sunny days. Few plants show the beneficial effects of welcome sunshine after a spell of wet cold weather quicker than do Roses. If such weather continue thorough syringings should be given daily, or green aphides will soon make its appearance. Even with the best of attention we generally get a slight attack during the spring months; but if fumigating is done as soon as the first signs of aphids is noticed there is not much difficulty in preventing injury.

Mildew is, perhaps, the worst pest we have to contend with in the Rose house, as when once it is thoroughly eradicated it frequently puts in an appearance again. Finally, ventilation is doubtless in many instances the primary cause of such attacks. The ventilators are, perhaps, kept closed for days together while the weather is wet and cold, and then too suddenly thrown open when bright sunshine comes. Provided a chink of air is given early on bright mornings it is always better to err on the side of under, rather than over-ventilation. Changeable weather such as we generally experience in March offers so many temptations to put air on too freely; the sun may be shining powerfully while a cutting wind prevails. Fear of getting some of the shoots scorched then induces many to give air too freely, and if the shoots near the ventilators are closely watched signs of mildew may be traced a day or two after. The time when syringing is performed is also a matter of some importance during changeable weather.

It is often a practice to wait until the house is closed before syringing is performed. This is, I think, a mistake, as at this season dull afternoons often succeed bright mornings; and in the case of late syringings the water rests upon the foliage during the time the temperature of the house is rapidly lowered. The plan I adopt is to syringe while the sun is powerful, whether it be at eleven, twelve, or one o'clock, the ventilators being closed when the sun loses power.

Another fruitful cause of mildew in the cases of Roses planted out is allowing the border to become too dry. Such borders are usually watered when the house is started, and if the soil forming the border is not heavy, by the time the first buds are visible it will generally require another application, if possible of liquid manure, or as a substitute, a dressing of one of the many approved chemical manures, thoroughly watered in. Such timely attention helps to put substance into both leaves and flowers, and renders them more proof against insect pests.

A cheap wash for destroying mildew is formed by dissolving 2 ozs. of soft soap in a gallon of water, and adding thereto a handful of sulphur; if this is thoroughly mixed and syringed on the plant it will kill every particle of mildew that it touches. There is, however, one slight objection to its use—viz., that the sulphur adheres to the leaves and rather spoils their appearance for a time. This is not of much consequence in the early stages of growth, but when the wash is applied just before the buds begin to open, the disfigured leaves spoil the appearance of the blooms, and when hundreds or thousands are ready for cutting at one time, it is an expensive business to clean the leaves. Richard's Mildew Insecticide is free from the above drawback, and is equally effectual.—H. D.

COLOURED IVY LEAVES.—Nothing could be more charming than the delicate tints of the common Ivy leaf growing on walls in some situations at this time of the year. I fancy it must be the condition of the soil that governs the colouration of leaves, as in a deep fertile medium the growth is invariably rank, and the foliage never changes from its dark green hue. I know of an establishment built of sandstone, the walls of which are partially covered with Ivy. With the exception of a small body of soil in which the Ivy was planted, the rooting medium is chiefly sandstone and rubble left near the foundations at the time of building. Consequent upon this the growth is never vigorous, and the leaves comparatively small. During the winter and early spring the latter assume a variety of tints, which are both charming and useful for decorative purposes. The varied colouring resembles very much the ripening tints of Vine leaves, and are generally most glowing near the points of the shoots. Some are almost yellow, others a reddish brown, and others again nearly crimson. Sprays of these tinted growths detached from the walls in lengths are very pleasing for decorations, and are often worn by ladies in preference to flowers. The leaves are also used largely in the make-up of wreaths, crosses, and other floral designs, for which purpose they are very suitable. I know of no form of wreath simpler and more charming than one made up of tinted Ivy leaves, with the flatness broken by the tips of leading shoots. Also for draping round pictures and ornaments in rooms sprays of coloured Ivy are elegant and effective.—H. H.

NYMPHÆAS AND BEES.

I WAS pleased to see a few notes on the above in the Journal, page 378, last vol., by Mr. Hudson; and although he does not at present explain the question, he has promised to make observations during the coming flowering season, and I have no doubt that the information he will give will be valuable and interesting.

Your contributor's remarks *re* the flies found in *N. stellata* is also identical with mine, and further, the notes given in a recent issue as regards bees will (as far as my observations go) also apply to flies. *N. alba* is visited by a large number of flies that are about the size and colour of the common honey bee, and they do their work in such a thorough manner that there is not the slightest doubt in concluding that they are the principal fertilising agents. This fly is also found dead in the flowers. Perhaps one or two may be found in every hundred blooms.

N. stellata flowers contain a greater number of dead flies with me—about fifteen or twenty to every hundred blooms. Although it is about the length of an ordinary bee the body is smaller, and it is nearly black in colour, and is quite distinct from the fly that is found in *N. alba*.

The observations I have made have caused me to arrive at the following conclusions:—The freshly developed flowers on the first day of opening contain a watery liquid at the base, which is surrounded by a well arranged circle of sepals. The second or third day of opening the sepals are irregular and more fully developed. Flies appear to favour the second or third day flowers, which are evidently visited with less risk, but should they accidentally or otherwise try to perform their mission on the fresh blooms they invariably get their bodies wet with the watery liquid. I have often seen them struggling to get out, but the sepals being so evenly placed they can only take hold of one or two each time, which is not sufficient to support them, consequently they are precipitated again into the liquid, and I think death is caused by exhaustion, assisted no doubt by the odour from the fresh flowers.

To support this I have on several occasions held on one side the flower containing the struggling fly, which has enabled it to crawl out, and after a few seconds it has taken flight, apparently none the worse for its bath. I have never yet observed a fly trapped in a bloom on the second or third day of opening.

Referring again to Nymphæas and bees; an article (page 393) by "Gardener and Bee-keeper," suggests that the climate may play an important part in controlling the fertilising agents. I do not hesitate in arriving at the same conclusion, for although the bees will seek for pollen from the Nymphæa flowers, it is generally during the first two or three hours they are open in the morning, and if the sun is by that time very high, most of them disappear, and their place is then taken by the flies referred to. Bees also favour the second or third day flower, but occasionally they will visit a flower on the first day or opening, and although they may go to the bottom I have only known a few instances where they have been trapped.

My present theory (which is based to some extent on facts) is that bees, or other fertilising agents, obtain pollen from distinctive species or genera that may contain an aroma peculiarly adapted to their taste and requirements, and allied species in close proximity are yet refused by them; it seems reasonable to suppose that by artificially fertilising the two species, the hybrids obtained would in all probability contain pollen that would be a combination of the two. In such cases these fertilising agents would acquire a taste for the hybrid, which would enable them to visit the flowers of the intermediate varieties, and also the original species.

As regards chance hybrid Nymphæas, I have not yet seen one obtained from naturally fertilised plants, and I think that plants generally retain their distinctive types and colours by natural fertilising agents. When, however, the natural laws are broken by artificial crossing, then the natural agents are again at work, and greater variations produced by their aid.

About eight years ago a friend of mine had a very large and beautifully fringed single white Hollyhock. I obtained some seeds which I saw taken from the plant. I sowed it early in spring in new ground, where native shrubs had been recently taken out. There must have been fully 100 seedlings, but very few had the Hollyhock leaf. After about two months from sowing they were flowering. The flowers were about 2½ inches across; some were white, some pink, but they were a distinct cross between the common Mallow and the Hollyhock. The few with the Hollyhock leaf remained true as far as the plant was concerned, and flowered the following season, but had pale yellow flowers that were not fringed like the parent. The others were annuals, which seeded freely and came up in the same place for two or three years without the slightest variation.—THOS. POCKETT, Malvern, Australia.

CLASSIFICATION OF INCURVED.

If I read correctly, Mr. Godfrey, page 142, says in several schedules he has received only the varieties classed as incurved can be shown in that section. The presumption is this, then, that those Societies alluded to will not allow any variety not included in the N.C.S. catalogue or list to be shown at their show. Surely this is somewhat a high-handed stipulation. Suppose during the current year a cultivator brings out an excellent Chinese incurved variety and desires to stage blooms in competition at the shows in question, cannot he do so because of some rule such as is outlined above?—SADOC.

LATE CHRYSANTHEMUMS.

FROM remarks made in a letter recently received from a friend who successfully cultivates late Chrysanthemums it does not appear there is any sign of this section waning, whatever may happen to the large bloom method of culture. Personally I think enthusiasm is increasing even in the latter section. Because one society (Watford) finds it necessary, or advisable, to wind up its affairs, that surely is no proof of a general decline in interest taken in the autumn queen. I know at least three new societies that are making a strong bid for public patronage in their initial attempt at establishing an autumn show. Such evidence is ample proof that the Chrysanthemum has not seen its last days yet awhile.

My friend writes:—"I am growing this season 35,000 plants made up in the following order: Elaine, Souvenir de Petite Amie, Niveus, and L. Canning 7000 each; W. H. Lincoln and Mons. Panckoucke 3500 each. Last season I had fourteen houses of Elaine alone!" Even such a collection as this gives but a faint notion of the number of plants cultivated by market men alone.—E. M.

SEASONABLE NOTES ON FORCING FIGS.

EARLIEST FORCED TREES IN POTS.

THE fruits will soon have completed their first swelling, and they then remain apparently stationary for some time. This is the most critical stage in their culture, and every care must be taken not to give a check, whether caused by excessive heat or want of moisture. In mild weather the temperature may be kept at 60° to 65° at night, but if cold 5° less will be safer. Progress is best made in the daytime by closing with plenty of heat and moisture, a rise being indulged in of 10° to 15° without producing a weak or elongated growth, keeping through the day with gleams of sun at 70° to 75°. Red spider must be kept under by copious syringing on all favourable occasions. Afford a steady supply of liquid manure to the roots, as Figs in full growth require generous support, and can hardly be overwatered provided the drainage is thorough.

PLANTED-OUT FIG TREES.

When these were started early in the year they will now require disbudding and stopping. Crowded growths must be thinned, but they are better prevented by disbudding, leaving no more shoots than space permits. Where extension or successional growth cannot be allowed the shoots may be pinched at the fourth or fifth leaf to form spurs, these giving good results in the second crop, but avoid crowding as the greatest of evils. In order to secure free and certain swelling in the first crop Figs it is advisable to keep the growths closely pinched for a time, as these are apt to appropriate the sap, and the first fruits suffer and fall in consequence when they are allowed to grow unchecked. Water the border freely when necessary at the temperature of the house or supply liquid manure, not too strong, and mulch with rich compost, which will attract the roots to the surface, where they can be fed by sprinkling with some appropriate fertiliser.

Where the trees are confined to narrow and shallow borders encourage the emission of roots from the collar or stem by placing pieces of fibrous turf and partially decayed manure in contact with it, and by extending the material outwards a number of feeders will be secured. If these are supplied with water or liquid manure, or top-dressings of artificial manures, they will greatly assist the second crop of fruit as well as the first. Keep the night temperature at 55° to 60°. When it reaches 65° by artificial means in the day admit a little air, increasing the ventilation with the temperature and reducing it in like manner, closing at 70°, syringing twice a day, and otherwise maintaining a genial atmosphere.

YOUNG TREES IN POTS.

Those intended for next year's forcing should be shifted into larger pots, and be placed in or over bottom heat. The compost may consist of

good yellow loam, with a fifth of well-decayed manure and a sixth of old mortar rubbish, adding a sprinkling of crushed bones, say a 6-inch potful to a bushel of loam. Provide good drainage, pot firmly, and do not let the shift exceed 3 inches in diameter that of the previous pot. Shade slightly from bright sunshine for a few days until the roots have taken to the new soil, when the trees should be fully exposed to light and sun. Pinch the growths at about four leaves to induce a bushy habit. The trees must be grown in all the light possible, so as to insure sturdy, short-jointed, thoroughly solidified growth.—GROWER.

NOTES FROM IRELAND.

ONE night's frost and two days' rain, then repeat the same again, seems to sum up the peculiar character of the passing winter. It is decidedly unpleasant; but vegetation does not appear to dislike the cold drenchings, for in spite of the chilling influence activity is apparent in the kingdom of silent life. In the garden knots of green have lately studded the Roses, and pale spear-points spring through the protective dead foliage of a goodly patch of Montbretia. What a progressive plant this Montbretia is, surely! Only six years since we planted a hundred of the Crocus-like corms; now one ventures to assert that a hundred thousand would be nearer the quantity in evidence.

The Doronicums, too—how glorious are these great, golden Daisies when well fed! Already a few buds are bursting into bloom, appreciated the more perhaps that, despite an open season, not many flowers have brightened up the dark days of winter. True, the proverbial Primrose has not been wanting. Primroses, like the poor, seem to be always with us. At present two long lines of hybrid seedlings display, in a measure, all the hues they are capable of so far as the bespattering down-pour will allow; but we would, I think, rather have them "coming in the springtime to tell of sunny hours."

Lately we wandered to the rocky slopes of Killiney Hill, a portion of which has been reserved to the public for ever in commemoration of our good Queen's Jubilee. Grand banks of a sturdy Veronica embellish some of the marine residences *en route*, and blooming profusely in mid-February as they were, left no question as to local suitability. Looking down from the dizzy heights of Victoria Hill the "Loch Fergus," a barque-rigged stately looking ship driven in shore and wrecked a few days previous, was a speaking witness of the wind-swept position. In the near distance, but comparatively sheltered, is St. Brigid's garden, that *multum in parvo* so tenderly cared for by the lady of the Anemones. Fine bits of natural rockwork are in evidence on the ascent to the hill, on the summit of which stands a puerile looking obelisk, which even 150 years of existence have failed to tone into harmony with the surroundings. With the exception of a couple of lesser monstrosities of the same crude conception Victoria Hill is left—and rightly left—to Nature and the citizens of the "cardrivingest city." On the sunny side sheets of golden Furze brighten the scene. The dedication of this fine bit of Nature's handiwork to the public was a fit offering to Freedom's shrine.

Below lies Dalkey, where a little coterie of sturdy "mum" growers abide; whom, judging by what one has seen and heard, are still as fever-smitten as when Mr. Molyneux and the writer discussed a tasty — together in one of their hospitable homes. Despite the above good examples, and some advantages of position, the Dalkeyites do not seem horticulturally inclined. So many of the humbler homes, which are naked, might be beautified by such plants as Escallonia macrantha, Fuchsia gracilis, and others which love the breath of the sea. A little inland, at the Alpine-like village of Enniskerry, we saw, some years since, charming masses of Lobelia fulgens in the tiny cottage gardens. However, note-taking, probably, should only include what is seen, but, possibly, is not purposeless in relating what is felt to be wanting. With this brief apology, Victoria Hill, and its environs, are left for higher ground in the gardening world.

As these notes are penned comes the intelligence of a home, whose name and fame are written high in the annals of gardening in the Green Isle, hereaved of its master. Few keenly interested in gardening have visited these shores without a run round picturesque Straffan in the plains of Kildare, and most will, I am sure, sympathise with the Hon. Mrs. Barton and her estimable head gardener, Mr. Bedford, who has ruled the horticultural department so ably and so long. Visits to Straffan have always made the pen run smoothly in depicting its glories; one can but dare to hope that no change may occur to leave them only memories of the past.

The retirement, lately, of G. M. Ross, Esq., M.A., from the secretaryship of the Royal Horticultural Society of Ireland, led to some 200 good men and true (including a new woman, I heard), applying for the post, which is now filled by the appointment of Mr. Hilliard. We trust he may be favoured by those fickle circumstances surrounding the field days, in order to carry on the good work of his predecessor, who, figuratively, pulled the old Society out of low water, and left it standing high and dry, well propped by a bank balance.—K., Dublin.

THE HISTORY OF THE PELARGONIUM.

(Concluded from page 153.)

THE Zonal race acquired importance subsequently to the large-flowering section. Those we collectively term "Zonals" were grouped by Sweet under the generic designation *Ciconium*, and the most important of this genus are *Ciconium zonale*, introduced in 1710, and *Ciconium inquinans*, introduced in 1714. These are the two parents of the race, no doubt, but their differences do not account for the fact that in the garden varieties we have every imaginable variation of leafage and of bloom. It is likely that *Ciconium reticulatum* of Sweet (143), a very distinct hybrid, gave the first touch to the variegation of the leaves, which has attained to such extraordinary development. In any case, this hybrid marks a distinct departure and appears to be well suited to be the founder of a race.

The "Nosegay" section is the oldest of the Zonals. The founder of this section is *Ciconium Fothergilli*, the figure of which by Sweet (226) would nearly serve to represent a good Nosegay of the present day, and it may therefore be concluded that the Nosegays have been less modified than the Zonals that represent *zonale* and *inquinans*.

Another early section is that with green leaves and pink flowers, of which we may consider *Christine* the modern type. This section is foreshadowed in *Ciconium cerinum*, which is admirably figured by Sweet (176). Here we have pubescent leaves and flowers of a soft rosy pink colour, the petals of which are beautifully rounded and nearly equal in size. Cultivators who remember *Lucia rosea* will have no difficulty in connecting the dwarf bedding Pelargoniums of the *Christine* class with this beautiful wax-flowered Pelargonium, which Sweet regarded as a true species.

The famous General Tom Thumb, a descendant of *Frogmore Scarlet*, and a competitor of *Huntsman*, *Cooper's Scarlet*, and many more that the General quickly vanquished from the field. This famous variety was raised by Mr. Wilson, gardener to W. Pigott, Esq., of Dullingham House, Newmarket, about the year 1842. It is said that as a seedling it was condemned and handed over to some children to be tormented, and very soon found its way to a dust-bin. But by some accident it was dragged from the dust-bin and planted, and as the summer advanced it manifested its character, and secured its fame and many more admirers than *Barnum's protégé*. But many persons have some kind of claim to the honour of raising Tom Thumb, for there prevailed during some fifteen years—say from 1840 to 1855—a mania for raising scarlet Pelargoniums adapted for bedding; for those were the days of the horticultural scarlet fever, and many varieties nearly alike came forth from various quarters. Many of these passed for genuine Tom Thumbs, and many perhaps were quite as good. However, the original and true variety differed from most of the others in this respect, that it rarely ripened a seed unless it was artificially fertilised, when it was as prolific as any. This fact separates it far from *Christine*, which is an inveterate seeder. The leafage also puts them far asunder, for Tom has a smooth papery leaf of a yellowish green, and *Christine* has a thick soft leaf of a bluish green—one takes us back to *inquinans*, the other to *cerifera*, and Nature ordered the characters ages ago in the solitudes that stretch away drearily to the west of Cape Town.

The pink-flowered *Christine* was raised by Mr. F. R. Kinghorn of Richmond in the year 1852. The parents were *Ingram's Princess Royal* and an old pink Nosegay, which was formerly much used for training on walls and pillars. The peculiar softness and blue tone of the leafage of *Christine* do not appear to be accounted for by the parentage, there being in it such evident traces of the *Cerinum* or *Monstrosum* of Sweet. Mr. Kinghorn, to whom I am indebted for its history, tells me that he very soon made note of its strong individuality, in which it seems to rise to the rank of a species, and reproduces itself freely and truly from seeds. During some fifteen years it was the most popular of all bedding plants, for it outran Tom Thumb at last. The beautiful *Rose Queen*, sent out in 1855, was one of the good things obtained by Mr. Kinghorn in the same batch with *Christine*. This has higher quality, but never proved so good a bedder, and therefore never attained to great popularity.

It would be unfair to omit all mention of the variegated-leaved varieties, because in a good bedding display they contribute features fully as important as the strong colours. They tone down and harmonise and divide. In the year 1844 there were very few variegated Zonals known, and only one with bright scarlet flowers: this was called *Lee's Variegated*, and was very scarce. It was, I think, raised by Mr. Bailey, then gardener at Nuneham Park. Mr. Kinghorn selected this *Lee's Variegated* to supply pollen for a cross on the old *Compactum*, which was the seed parent, and in the first batch of seedlings from this cross he obtained the celebrated *Cerise Unique*, and the much more celebrated *Flower of the Day*, the most useful and most famous of all known variegated-leaved Zonals. Mr. Kinghorn considered this was the greatest advance ever accomplished at one bound in work of this kind, and I thoroughly agree with him. The large seedling plant and two smaller plants of *Flower of the Day* were purchased by Messrs. Lee in August, 1849, and in August, 1850, they had a stock of 1500 plants of various sizes to offer for sale—a wonderful sight in those days, and one worth seeing even now.

It so happens that the last-named, most useful of all the silver-leaved varieties, conducts us direct to the fountain head of the whole race of the tricolors. In the year 1850 Mr. Kinghorn raised from *Flower of the Day* the beautiful variety known as *Attraction*, the leaf of which has a silvery margin and a dark zone, diffusing subdued rays of red and rich brown outwards upon the creamy band that girdles it. The *Attraction* was the first silver tricolor, and one of the parents of the first golden

tricolor. Mr. Grieve, in his admirable History of Variegated Pelargoniums, tells that he fertilised a dark-zoned variety known as *Cottage Maid* with the pollen of *Attraction*. Amongst the seedlings occurred one that was the parent of the dark-zoned Emperor of the French, from which came the whole race of golden tricolors. From *Cottage Maid* and *Golden Chain* (the latter being the pollen parent) Mr. Grieve obtained *Golden Tom Thumb*, and from Emperor of the French and *Golden Tom Thumb* (the latter being the pollen parent) he obtained *Golden Pheasant*, the first true golden tricolor. This same Emperor of the French, grandson of *Attraction*, produced by the pollen of *Golden Pheasant* two famous tricolors, *Mrs. Pollock* and *Sunset*.

The double Pelargoniums have had a career of fifty years at least. A handsome double purple, named *Veitchianum*, not of the zonal section, but allied to *Barringtonia*, was raised by the late Mr. J. Veitch at Exeter about the year 1828, and its portrait appears in Sweet's supplementary volume (81), where nearly next door to it is another double named *Implicatum* (86).

But the proper history of the doubles begins with *Wilmore's Surprise*, a handsome semi-double variety, which was described and figured in the "Gardeners' Chronicle" of August 17th, 1850. This was found by Mrs. Wilmore of Strawberry Vale, Edgbaston, growing in the midst of a plantation of *Hollyhocks*, and so unaccustomed were the eyes of the florists to such a thing that it was considered to be a true hybrid between a Pelargonium and a *Hollyhock*. A remarkable fact in the history of this variety is that simultaneously with the finding of it in the garden at Edgbaston it was obtained by the late Mr. Beaton as a sport from *Diadematum rubescens*, and was by him named *Monstrosum*. The Edgbaston plant was shown by Messrs. Lee of Hammersmith at Regent's Park on the 30th of June, 1852, and Mr. Beaton suppressed his *monstrosum* in favour of it.

The double Zonals are of later date, one of the earliest being the crimson-scarlet *Gloire de Nancy*, which was first shown in this country in the year 1866. In the year 1869 there were seventeen double Zonals brought into public notice, and of other sections in that year the collective name was *Legion*. At this point of the story the subject becomes too large to be handled on the present occasion. It is quite certain that during the few years when *Geraniums* were everything and all other vegetables nothing in human estimation the heads of gardeners were so crammed with zones and margins, and trusses and pips and beds, that there was no room for anything else, and the phenomena of the tulipomania were reproduced in a newer fashion, and no one was fully aware of the fact that the world had gone mad on the subject of Pelargoniums.

Now that we can again survey the subject calmly it will be observed that two classes of Pelargoniums remain in full favour with the public. The large-flowered show varieties and the large-flowered single Zonals take the lead, and they are pleasantly followed by a crowd of lily-leaved, double-flowered, and variegated sorts that are useful and beautiful, but no longer oppress us by their multitude and similarity. A severe standard of judging has been set up, and a variety must be distinct and good to pass through the sieve. Moreover, the raising of varieties has been to a great extent reduced to scientific principles, and we obtain as a result new characters suggestive of the great extent of the field that still lies open to the adventurous spirit in cross-breeding. No one in recent years has contributed more directly towards the scientific treatment of the subject than Dr. Denny, of whose labours I propose to present a hasty sketch.

Dr. Denny commenced the raising of Pelargoniums in the year 1866, having in view to ascertain the influence of parentage, and thus to establish a rule for the selection of varieties for seed-bearing purposes. In raising varieties with variegated leaves, as also with distinct and handsome flowers, he found the pollen parent exercised the greatest influence on the offspring. The foundation of his strain of circular-flowered Zonals was obtained by fertilising the large starry flowers of *Leonidas* with pollen taken from the finely formed flowers of *Lord Derby*. From 1871 to the present time (1880) Dr. Denny has sent out sixty varieties, and he has in the same period raised and flowered and destroyed about 30,000. These figures show that when the selection is severe, and nothing is allowed to pass that is not of the highest quality, there must be 500 seedlings grown for the chance of obtaining one worth naming. The late Mr. John Salter used to say that it was needful to flower 2000 seedling *Chrysanthemums* for the chance of one worth naming. Therefore, if the comparison is of any value, it shows that raising Zonals is a very profitable business, the chances of success being four times greater than with *Chrysanthemums*. But Dr. Denny obtains more good things than he sends out, for he makes every year a selection of plants for seeding, and these amount to about 3 per cent. of the total number. It will be seen, therefore, that for every one sent out under name there are about fifteen equally good, or nearly so, but for some reason or other they are not parted with, but are reserved to supply seed or pollen, and are then destroyed to make room for a new selection.

Amongst many interesting results of our friend's observations is one that strikingly confirms a suspicion that accompanies a study of Sweet's portraits—it is that some varieties assume the character and bearing of species, and by self-fertilisation reproduce themselves with peculiar exactitude. No one can doubt that many of the so-called species of plants, whether of Pelargoniums at the Cape or of Willows in England, are as truly hybrids as any that are raised in gardens. And this brings us to the question, What is a species? and the question suggests that if in treating this great subject I scarcely knew where to begin, I certainly know where to leave off. I confess I do not know what is a species—and so, thanking you for your kind attention, I now return to the golden silence.

MUTISIA CLEMATIS.

THIS, "J. R.," is an ornamental plant, the long tubular bright red flower heads drooping from the slender climbing stems supported by neat pinnate and tendril-terminated leaves having a graceful appearance in suitable situations. It succeeds very well in a greenhouse trained to a pillar or short rafter, but the plant requires a position where it can be readily seen. It can be planted out or grown in pots, a compost of loam, peat, and sand suiting it well, with plenty of water when in growth, and a well marked period of rest subsequently. Fig. 34 represents a bloom of this beautiful, though seldom grown, plant.

DEEP POTTING AND PLANTING.

THE question of planting Tomatoes deeply may be applied to other plants also. Personally I do not believe in earthing up say 6 inches to a foot of Tomato stem at one operation, but always advocate planting low down in the boxes or pots in shallow soil, and when this is permeated with roots adding an inch at a time as necessary until the limit of soil capacity is reached. No plant better responds to frequent top dressings than the Tomato. As the fruit develops, a little enrichment varied from time to time with soot or the excrement of sheep, horses, or fowls in limited quantities separately is excellent. These applications induce the white rootlets to break from the stem, and joining their predecessors eagerly run through the food mixture, provided so to speak in relays, and the plant progresses without lack of energy for all requirements.

This would seem the more natural treatment. I am a thorough believer in the efficacy of judicious top dressings where practicable, and this belief surely is universal, or wherefore the dressings annually given to Peach trees and Vines, while the shrubberies have theirs in fallen leaves forked in year by year. Again, the farmer carts soil, road sidings, or manure on to his grass. Surely we have enough depth of soil here. But that is not the object: he well knows that these annual top dressings prove a healthy stimulant to his grass crops, new roots form, and as the sun increases in power, two or three blades of grass shoot up where probably only one would have grown under less favourable treatment. This should convince every thinking man of the necessity of maintaining a healthy root action by periodical dressings as recommended.

With ordinary plants in pots we see the same misconception. Of course one cannot very well apply the process recommended for Tomatoes to all, but no one will deny that frequent pottings in the case of such quick growing plants as Cinerarias and Calceolarias are preferable to giving unduly large shifts from small to big pots at one operation. I am for this reason averse to layering Strawberry runners directly into their fruiting pots on the assumption that a second potting supplies something that was lost in the former system ere the roots derived any benefit therefrom.

But to revert to deep potting. I have repeatedly proved that various plants, such as Begonias, Gloxinias, Hyacinths, Tulips, Lilliums, Gladioli, and many others do equally as well potted deeply as otherwise. I never had better seedling Gloxinias than I grew last year, and these being drawn somewhat through no fault of mine, I let them down nearly to the bottom of the pots, and no plants could have thrived or flowered better. Some growers allow the corm of Cyclamens to rest on the soil; I prefer them with the crown only clear, as I am convinced there is much more danger from shallow potting or planting than is to be feared in the other instance with the above plants.

There are of course times when it is necessary to alter the general rule of planting. In summers like last, the winter Greens, Brussels Sprouts and Broccoli stood best, when, although leggy, they were planted deeply with a crowbar and afterwards had soil drawn up to their stems. But in every instance where practicable, constant feeding judiciously given from time to time when needed will never be misapplied, especially to such gross feeders as Cucumbers, Melons, Vines, Peaches, Tomatoes—in fact all fruit bearing plants are better top-dressed than potted afresh. I should like to see other opinions on this matter.—A MIDLAND GARDENER.

DEEP POTTING TOMATO PLANTS.

"A." (page 144), seems to doubt the utility of potting young Tomato plants deeply, and hints that only those who wish to hide bad culture adopt it as their primary object. The best practical growers do not bury the stems when potting for that reason, but because they find even the sturdiest and healthiest plants benefit thereby. Why should top dressings be given strong plants in a fruiting stage and thus encourage roots from the stem if the practice is not beneficial?—E.

"A." appears to be somewhat sceptical as to the good results obtained by the above practice, as recommended by "Observer," and endorsed by "E. D. S." If I do not mistake the identity of "A.," we all know him to be a wielder of the pen who is cautious in the extreme, and this to prevent us all from doing anything rash. Before he sanctions the practice of deep potting or planting as being a good one, he would like to hear of some practical grower experimenting by planting six plants of one variety in the ordinary way, and a similar number with their stems buried 4 or 5 inches. "A.'s" wish has been anticipated on a far larger scale than he proposes. Last year I planted a house with Challenger; four rows of plants were employed, and as some of the plants were leggy, the stems were buried quite 4 or 5 inches. Yet the whole of the plants were a

pronounced success, the two central rows attained a height of 7 feet, and fruited right to the top, in fact I never saw a heavier crop. It sounds well to write against deep planting to hide bad culture, but when thousands of plants are grown some of them are sure to become comparatively leggy.—H. D.

PERENNIAL BORDER FLOWERS.

(Continued from page 52).

ADENOPHORAS.

THESE plants are not at all largely grown, probably because they do not lend themselves readily to division. The only satisfactory way of propagation is by means of seeds, and it is advisable that these should

FIG. 34.—MUTISIA CLEMATIS.

be sown where the plants are to grow, or in small pots, from which they can be planted with the ball of earth attached. They have thick, fleshy roots, which are impatient of disturbance, and like a fairly strong soil with a rather moist subsoil. A sunny exposure is best. Out of a considerable number known only a few are to be found offered, and seed lists, even of specialists, show that there is little choice.

In catalogues of the current year, *A. denticulata*, *A. Lamareki*, *A. lilifolia*, and *A. Potanini* are the only species of which seeds are for sale. They generally resemble each other in their long spikes of drooping flowers, much like those of the Campanulas, from which only a small botanical distinction separates them. Of those named above *A. Lamareki* and *A. Potanini* grow about 18 or 20 inches high, the others being about a foot taller. The flowers of all are blue. Those of *A. Potanini* are larger than the others. The Adenophoras come from Dahuria and Siberia.

ADONISES

Plants bearing the name of Adonis ought to be handsome, and it may be said that few, if any, discredit the name. Not many are finer than the

well-known and general favourite *A. vernalis*, which about March yields us so freely its handsome yellow flowers. It ought, however, to be left undisturbed as long as possible if we are to have a good display. Earlier than it is the newer *A. amurensis*, a desirable plant, also with yellow flower, which is now considerably cheaper than it was a few years ago, *A. wolgensis* comes in between *A. vernalis* and *A. pyrenaica*. It also has yellow plumes. The fine species *A. pyrenaica* is a little taller than *A. vernalis*, and because of its later blooming habit is of less value to many flower growers, as by the time it comes into bloom other flowers are more plentiful.

These are the best of the perennial Adonises, and grow from 9 to 12 inches, or a little more, in height, this depending upon the character of the soil and the amount of moisture. They can be propagated by division when large enough, or may be raised from seeds. The latter is a slow process, as the seeds germinate slowly unless fresh, and plants are some time reaching a flowering size. There is every probability that these showy plants could be improved by raising and selecting seedlings; some plants of *A. vernalis* are much better than others.

ÆTHIONEMAS.

While these pretty Crucifers can, in some gardens, be grown in the choice border, they are better suited for the rock garden, and will not at present be treated of in detail. It may be said that *Æ. coridifolium*, rosy lilac; *Æ. grandiflorum*, rose; and *Æ. pulchellum*, rosy lilac, have been successfully cultivated in borders of light soil in warm gardens. They may be raised from seeds or cuttings.

AGAPANTHUSES.

Well known as a splendid plant for tubs or large pots, the *Agapanthus* or "African Lily" is only found as a hardy plant in southern gardens. There is an exception, however, which ought to be more largely taught, and this is that a small-flowered species, named *Agapanthus minor Mooreanus*, is quite hardy in the United Kingdom, except in some exceptionally cold districts. It has rather narrower and shorter leaves than the popular *A. umbellatus*, and the blooms, which are also produced in heads, are smaller than those of that species. The height of the flower stem is often stated as 18 inches, but this is variable, and with the writer a few inches more are usual. *A. minor Mooreanus* is increased by division, but may also be raised from seeds, which are obtainable from some seedsmen.

AJUGAS.

A great defect of the *Ajugas*, or Bugles, is that of running too freely by means of stolons, and thus encroaching on other plants to the detriment of the latter. Yet they have their merits and uses, and it kept within bounds are valuable in their way. One of the best of the genus is *A. genevensis*, which is generally seen with blue flowers, although there are white and also rose varieties. It grows from 6 to 12 inches high. It is said to thrive best in bog soil, but with the writer it has grown luxuriantly in light, dry soil. The finest blue variety is known as *A. g. Brockbanki*. This has very dark flowers, and also darkish leaves. It is troublesome because of its underground stolons, which come up where their absence would be preferable.

A. orientalis needs a warm place, and does not do well in many gardens. It grows rather over a foot high, and has whorls of blue flowers. Of some value in the garden to cover waste spaces or trail down rockwork are the dark-leaved and variegated forms of *A. reptans*, the common Bugle. The former has exceedingly dark leaves, resembling in colour the best of the dark-leaved Beets. They are, it is perhaps as well to say, much smaller. The variegated-leaved variety is very prettily marked with creamy white. Neither of these should be allowed to flower. *A. pyramidalis*, a native plant, is sometimes grown in gardens. It has blue flowers, and there are also purple varieties. The Bugles are increased by division.—S. ARNOTT.

(To be continued.)

THE BEST PEACHES.

IN conversation with a market grower of Peaches quite recently, he told me that he had discarded Royal George owing to its susceptibility to mildew. Such testimony as this is quite opposed to the selection of "H. D.," p. 119, who classes this variety as the best of Peaches. Personally I think it an excellent Peach when mildew is absent. I am aware, too, that "H. D." may reply there should be no mildew in a well-managed Peach house. In spite of this assertion, though, we find mildew where the least expected, especially if cold east winds prevail for several days during the month of May, combined with a hot sun. Cultivators are then tempted to admit more air through the front ventilators than is wise, and mildew might often be traced to this cause.

The selection of six varieties for the open air given by "H. D." I consider so good that I should wish but one change—viz., substitute Bellegarde for Royal George. The former produces large, handsome fruit, exceptionally high in colour on the sunny side and very rich in flavour. For growing under glass, I do not think Alexander is good enough to rank amongst the best three. The flavour is only moderate, and I would rather plant two trees of Waterloo than one each. Walburton's Admirable, I think, should find a place in the list of late varieties. It is a sure cropper under ordinary circumstances, grows to a huge size, while the flavour leaves little to be desired. For midseason growth I uphold "H. D." in his selection, especially in the inclusion of Violette Hâtive, of which I think very highly.—E. MOLYNEUX.

THE YOUNG GARDENERS' DOMAIN.

YOUNG MEN'S DREAMS.

No truer article and more to the point was ever written than that on page 99, and it should appeal forcibly to all young readers of the Journal. What is said about many young men after being a year or two in some institution where horticulture is taught is perfectly correct. They have only got the rudiments of gardening; principally theory and what the text books afford, and have little idea of the practical aspect. There is no one who believes in science in relation to horticulture more than myself, but without practice it is of little use. Gardening may be a pleasant occupation to some; but the same might be said about many another trade. There are dirty and rough jobs in connection with gardening, and it is the men who do not turn up their noses at the dirty work, but take an interest in everything, from wheeling manure to decorating a dinner table, that make the best gardeners.

It seems to me that there are too many gardeners being "manufactured," especially when we consider how many are turned out every year from private gardens and nurseries, not to speak of institutions. It would be better if it were made known to all young lads who are thinking about starting gardening what was expected of them and what they may expect. It might then save many a pang afterwards, and also keep many a "weed" from a garden. Although this is nothing in connection with the culture of any plant it is a subject that deserves to be discussed, and I hope to see a few remarks from some other young hands in the domain.—THISTLE.

OUR FRIEND THE TOAD.

YOUR correspondent "Parvo" (page 124) has not had an experience altogether unique in seeing a toad eat ants. About two years ago we were troubled very much by woodlice in our Melon house, in which hotbed material is put, and a ridge of soil runs on the top the whole length of the house in which the plants are placed. At night this bed became swarmed with woodlice of various sizes, also quantities of small black ants. The former pest ate the foliage that came in contact with the soil, and also ate small holes in the leaves attached to shoots which were tied to the horizontal wires above, while the ants completely cleared the flowers of pollen as soon as developed. These busy little insects seem to work incessantly night and day.

I therefore captured a couple of toads, which are rather scarce in the district, and put them in the Melon house, where they soon made themselves at home by burrowing in the soil, and sleeping all day. Every night when going through the houses at 10 P.M., I used to hunt up the toads and watch them; at first they seemed to avoid the light of my lamp, until one night I caught a good fat woodlouse and placed it on one of the toads' back, off which it soon scrambled and ran in front of the toad; the latter made a move forward, and putting its tongue out with a snap, tried to lick in the insect, and after three similar efforts the woodlouse disappeared in the somewhat capacious mouth of the toad. Every night after I used to catch the woodlice and throw them in front of the toad, which promptly showed its appreciation. It was surprising how tame it became.

The toad much preferred the woodlice to the ants, which latter I found it necessary to tempt from the flowers by placing a few small jars of sugar and water thinly mixed close to the stems of Melons, into which quantities went to partake, and were drowned. When entering the house one night at my usual hour, and about six weeks after the toads' incarceration, I was alarmed to see my friend the toad kicking about in a most unusual way. On closer inspection I found it was trying to slip its skin. While watching its struggles to free itself, I thought I should be the happy possessor of a toadskin, but after using its hind and fore feet a great deal it succeeded in getting the skin over its head into its mouth, and with one gulp it was swallowed, after which it crawled away in a new outer skin, which looked quite glossy, and two days afterwards no one but myself could believe so marvellous a change had taken place. I doubt if many persons have witnessed a similar occurrence. The temperature of the house was 75°, after a very warm day.

Another good way to trap woodlice is to have some small seed boxes, in the bottom of which put some dry moss; examine these every morning over a pail of hot water, and if any are in the box shake them out into the pail. Sugar and water, in which a little arsenic is mixed, will also destroy the ants.—FOREMAN X.

THE HOME OF SHERRY.—This is how Jerez, from which sherry takes its name, is described in "Sell's Commercial Intelligence," by one who has recently visited that quaint picturesque spot and become acquainted with the community there. The streets are wide, and dotted with Orange and Acacia trees; and several squares are made quite gay with flowers and shaded with Palms or other umbrageous foliage. The market-place is bright and lively; and the numerous rows of snow-white houses, with emerald mouldings and balconies, indicate that the inhabitants are in favoured quarters. But the chief attraction of Jerez is the wine stores, which are built on the outskirts of the town, and surround it as with a breastwork. The Vines, clinging to the chalky slopes and ridges of the more distant hills, are reared on a white compact soil termed *albariza*, from which the highest class wines are derived, and develop, when matured, a remarkable flavour. The coarser qualities of wines are produced from Vines on the lower slopes and valley from a dark alluvial soil. Hence the best sherry is produced from a magnificent Grape grown in exceptionally suitable soil under most favourable climatic influence, and Vino de Jerez has no superior among the white wines of the world.

HARDY FRUIT GARDEN.

Culture of Cob Nuts and Filberts.—To establish a plantation of Nuts young suckers should be obtained from fruiting bushes and planted, shortening them to 1 foot. A light and open position suits Nuts, with soil of a friable character, and having a well-drained subsoil.

Growth the first season must be confined to one stem, and this encouraged to grow erect and vigorously. The following season shorten to 18 inches, and when fresh growths push select six of the best placed. Train these to a hoop, tying them on the outside, so as to form a basin-like framework. The next season the six shoots must again be shortened to about 4 inches, which will result in securing twelve shoots if two are trained from each. When side growths push pinch them to five leaves, and encourage the main branches to extend until of the desired height. This method of training Nuts keeps the bushes open in the centre. Sunlight and air can freely circulate, and spurs of a fruitful character ensue.

Pruning.—The leading growths require shortening to cause the production of side growths during the formation of the bushes, and closely shortening after the bushes are fully formed. The side growths produce the flowers. When the small pink pistillate blossoms have opened, and the catkins or staminate flowers have shed their pollen, the pruning may be carried out. The shoots bearing catkins may then be shortened closely back, as these are invariably long. Unfruitful wood may also be dealt with similarly. Strong sappy shoots can be entirely removed. Twiggy shoots with blossom buds at the points must be retained entire. Cut back old fruiting shoots to half an inch of the base. Do not allow spurs to become too crowded or elongated, and when a branch is declining in vigour from any cause, select a promising growth from the base to take its place. Keep the bushes well balanced with wood of medium strength.

Planting Strawberries.—A piece of good ground, thoroughly well prepared by deep digging and liberal manuring in the course of the winter, should be selected for spring planting of Strawberries. The young plants for the present planting ought to be those which were late or small in size at the time of the autumn planting, and in consequence were inserted in small beds close together, for the purpose of strengthening before finally placing in permanent rows. Such plants will lift from their winter quarters with plenty of fibrous roots and soil attached. New stock which has to be procured seldom has roots with soil attached, therefore the fibres must be carefully spread out on small mounds of soil, and properly covered.

Soil that is very light should be well trodden before planting, and the ground must be made firm about them afterwards. It is better not to mulch between the rows at first, so that the soil can have the benefit of sun and warmth, which will cause growth to be vigorous. Hoeing between the plants can be practised frequently for the purpose of keeping down weeds and accelerating growth. In May a light mulching will then be of advantage, and tend to the conservation of moisture. If flower trusses show on these plants promptly nip them out, for by no means are the plants strong enough to bear fruit the first season.

Blackberries.—The cultivated or garden forms of Blackberries like to grow in a sheltered position where strong winds cannot damage them. They require soil of a rich strong character. Before planting it ought to be deeply cultivated and enriched with manure in a decomposed condition. The Parsley-leaved variety is one of the best. Planting may be done now if healthy young plants with a fair number of fibrous roots are procurable. Insert them 5 feet apart in the row or position selected. If several rows are planted the distance between them ought not to be less than 8 feet. Cut the plants closely down after planting, so that the resulting growth may be as strong and vigorous as possible.

In every way they need similar treatment to Raspberries, except in the training, which necessitates the long canes Blackberries produce to be laid-in to the stakes or trellis in a more or less horizontal manner. A close form of trellis is not absolutely requisite, but stakes may be firmly fixed 2½ feet apart, and the canes trained upon them. It will probably take two seasons to establish good fruiting plants. Plenty of manure must be applied annually, because, like Raspberries, they are gross feeders. Retain the best canes annually, and cut out the weak. Four or five will be enough for each stool.

Completing Pruning.—All pruning of fruit trees and bushes should be completed forthwith. Sap is now becoming active, and there is a loss of force when pruning is done very late, because the sap which ought to have been stored in the fruit buds is distributed in a number of superfluous growths. When the prunings have been cleared away dress the ground between Currants, Gooseberries, and Raspberries with manure.

Gather all prunings of trees and bushes, as well as other rubbish, into a heap and burn them. If the burning is done steadily, more in the way of a smother than a fire, a valuable heap of charred refuse will result. This can be spread over the roots of trees and bushes, and it will act beneficially in furnishing potash.

FRUIT FORCING.

Cherry House.—The main art in forcing Cherries is attention to the ventilation; a free circulation of air should pass through the house whenever the temperature exceeds 50°, the amount of air being regulated by the condition of the outside atmosphere. Fire heat need only be employed to prevent the temperature falling below 50° in the daytime, and to maintain a night temperature of 40° to 45°. Attend to fertilising the blossoms with a camel's-hair brush or a feather. Aphides generally appear just as the trees set their fruit. They must be destroyed, or they will ruin the growths and spoil the Cherries. Grubs also infest the foliage; one kind of caterpillar rolls itself up in the leaves, and can be extirpated by squeezing, but another encases itself in a web on the under side of the leaves, and they appear as if scalded, and from the foliage the pest makes its way to the flowers and devours them. The surest means of riddance is to examine the trees occasionally and destroy the grubs.

Peaches and Nectarines.—*Earliest House.*—Now the fruit is stoning the temperature must be kept as equable as possible. Too high a temperature, especially at night, is not favourable to the process, and sudden fluctuations often cause the fruit to drop wholesale. The temperature should be continued at 60° to 65° at night in mild weather, 55° to 60° when severe, 60° to 65° on cold dull days, 65° to 70° when mild but sunless, 70° to 75° with gleams of sun, ventilating early and freely under favourable climatic conditions. Thinning the fruit must be seen to, not allowing twice as many fruits to stone as are to be left for the crop, but a few more than the required number should be retained to meet casualties in stoning. One fruit to a square foot of trellis covered by the trees is a capital guide. Small fruited varieties may have the fruit left a little closer, and vigorous trees will carry more than weakly trees. Overcropping, however, must be strictly avoided. Nectarines require the same space as Peaches to have fine fruit.

Secure all the shoots to the trellis as they advance in growth, stopping any that are likely to exceed 12 to 15 inches at those lengths, and if the pinching results in laterals stop them at the first leaf. Shoots retained to attract the sap to the fruit should be stopped to one leaf. Extensions must be trained in their full length, pinching laterals at one joint as made. Syringe the trees in the morning and afternoon when the days are fine, but damping the paths and borders will be sufficient in dull weather, with an occasional forcible syringing to keep red spider under. If the pest gain a footing extirpate it by the prompt application of an insecticide or a solution of petroleum emulsion, carefully following the directions for use. Inside borders must be kept duly supplied with water or liquid manure in a tepid state, but avoid over-stimulation whilst the fruit is stoning.

Second Early House.—Disbudding must be proceeded with gradually, and the successional bearing shoots should be laid in as soon as they are sufficiently advanced in growth. Thinning the fruit must be attended to after the remains of the flowers are cast. Remove all twin fruit, the smallest, that on the under side of the branches, and the badly placed, leaving three on a branch of 12 inches length, to be afterwards reduced to two on a strong, and one on a weak branch, when of the size of marbles. Only one fruit, as a rule, should be left on each bearing shoot, but two may remain if there be a deficiency in other parts of the tree. The fruit will rapidly swell to the size of small Walnuts, the temperature by that time having been increased to 55° to 60° at night, 60° to 65° by day from artificial heat, and 70° to 75° from sun heat, with a free circulation of air from 65°, avoiding cold and drying currents. Syringe the trees twice a day in bright weather, and occasionally in dull weather, with damping of the floors once or twice a day will keep red spider under and maintain a genial atmosphere.

Succession Houses.—Trees now in bloom require a free circulation of air, or such as will keep the atmosphere buoyant with sufficient fire heat to prevent sudden depression of temperature, maintaining 50° at night, or a few degrees less on cold nights. A temperature of 50° to 55° will be suitable in the daytime, advancing to 60° or 65° from sun heat with free ventilation. Shake the trellis or trees occasionally to distribute the pollen, or preferably, pass a camel-hair brush or feather over the flowers that have ripe pollen once a day, and give extra attention to the shy-setting varieties by conveying pollen from others that produce it in abundance, as, for instance, Royal George and Stirling Castle Peaches, also Elruge Nectarine. Keep the paths well damped on fine days, and be more sparing of water when the weather is dull and cold.

Late Houses.—The roof-lights need not be put on until the buds show the silvery integuments that envelop the floral organs, but they are not safe after the blossoms show colour. Trees under fixed roots are more forward, the buds being in various degrees of expansion. Where syringing has been practised it must be discontinued as soon as the anthers show clear of the corolla, but damp the floor in the morning and afternoon, leaving a little air on constantly at the top of the house. No more fire heat should be used than is absolutely necessary, but after the flowers show the stamens a certain amount of warmth is needed, for when the atmosphere is cold and moist, and the flowering extends over a considerable period, the fruits do not set well; therefore after the blossoms open maintain a temperature of 40° to 45° at night, 50° to 55° by day artificially, with a free circulation of air, advancing to 65° with sun. In the case of weak trees having a superabundance of blossoms, it is advisable to remove the flowers from the under side of the shoots or the back, as the trees may be against front or back trellises. The borders must be kept healthfully moist, and weakly trees may be supplied with liquid manure.

THE BEE-KEEPER.

SEASONABLE NOTES.

THE favourable change in the weather will have been taken advantage of by bee-keepers to make a thorough examination of stocks without injury to either bees or brood, which is unusual at this early date. It is important that bee-keepers should know as early as possible the condition of each individual stock in the apiary. Often in a backward season this cannot be done for at least six weeks after this time. We do not recommend a useless manipulating of the bees during the dull short days of winter; but when the operation can be carried out under favourable conditions, it is a decided advantage. We then know what treatment is necessary to bring each colony to its full strength, so as to obtain a surplus from whatever source may be within reach of the apiary in that particular locality.

In some districts an early harvest is obtained from the fruit tree blossoms. Others again depend chiefly on the field Beans and White Clover, whilst some take a large surplus from Mustard, and last of all the Heather plays an important part in yielding a handsome return for the labour bestowed on the bees.

As the above are some of the chief honey-producing trees and plants in this country, and flowering as they do at different times, it shows how necessary it is for the bee-keeper to make arrangements so as to have his hives crowded with bees when the honey flow comes.

It is encouraging at this early date to report that all the stocks recently examined are in excellent condition. The bees are numerous; more so than they often are at the end of April. Breeding, too, is going on apace. In some of the strongest colonies there are several frames of brood in various stages of development, and as the early spring flowers are now plentiful, within easy reach of our apiary, the bees are working freely on them, and this is doubtless one reason why they are doing so well. The real pollen obtained from flowers is preferred to the artificial article.

USING DARK HONEY.

As dark honey was so plentiful last season, many bee-keepers doubtless kept it in stock for feeding purposes. We have often heard it stated that honey that has been spoiled for commercial purposes by the admixture of honeydew should also be condemned for feeding purposes. The past season, however, has exploded that fallacy, as we can testify from personal experience to never having had bees in such good condition before, and they were all fed on dark honey. During our recent examination we found many of the combs quite perfect, and not a cell uncapped. These were in the top storey on hives which were doubled last summer, and were left in this condition throughout the winter. We shall have something to say on this system in future notes. At present it suffices to say that all are in perfect condition, which shows how advantageous it is to sometimes leave the beaten track and experiment on new lines.

Hives that are short of stores, owing to the removal of part of the surplus last autumn, may now have a couple of frames of sealed stores given. One side of the comb should be slightly bruised before being placed in the hives. This will cause the bees to commence breeding at once. The combs containing stores ought to be placed on the outside of the brood nest, allowing at least half a dozen empty combs, or those partly filled with stores, in the middle of the hive. The queen will thus have ample room for ovipositing. If there are not sufficient empty cells her laying powers would be retarded.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Cutting-back Cedar (H. T. H.).—The stems, 3 to 4 inches in diameter, of trees twenty-five years planted, do not usually break again when cut down to within 3 feet of the ground. As, however, they have been clipped at the lower part, there is a possibility of buds remaining dormant at the base of the branches next the stem, and starting on the trees being cut back as you describe. We should certainly try them, operating towards the end of March and during warm moist weather. About the Box and Yew recommending there need be no question, as they shoot freely from the stems, of course, when these are living, and soon form excellent screens with due attention to regulating the young growths. The best time to cut back both Box and Yew is during mild weather in April, and it may be done as much as desired, even to the bare stem, and to 1 foot from the ground.

First Crop for a Neglected Garden (Somerville).—The first consideration is to remove all weeds of a perennial character by the roots and burn them. Then spread the ashes on the ground and have this well dug with a fork, giving a coating of manure, if necessary. As the greater part has been used for a fowl run it will perhaps be quite rich enough without manure, and give little trouble as regards weeds. We should not hesitate to sow or plant any kind of vegetables desired in it the first season, but as you particularly mention "first crop," we may say that not any equals Potatoes, for they require cleanly culture, and leave the land in good condition for succeeding crops. If the ground has any grass other than couch it may be desirable to trench it, and thus get rid of the weedy surface, as well as deepen the soil for growing crops. All perennial weeds, such as bindweed, docks, dandelion, and especially couch and the creeping bent grasses, must be carefully extracted.

Vines from Eyes (H. S.).—It is not possible to secure strong canes from eyes inserted now, and with no special means at command to forward them, such as are suitable for fruiting in pots the following year. To do that the eyes must be inserted not later than the early part of February, be given bottom heat to start them quickly, potted as soon as rooted, shifted into 6 or 7-inch pots by this time, and when these are filled with roots transferring the Vines to 12-inch pots. The Vines must have a light well-heated house, with a temperature of 60° to 65° at night, 70° to 75° by day, and 80° to 90° from sun heat, training the rods about 1 foot from the glass. As you can only get canes 12 to 18 inches in length and of penholder thickness the first year, you should act on the cut-back system—namely, cut the one-year canes down to one eye, allow these to start and grow a few inches, then turn out of the pots, shift into 6 or 7-inch pots after removing the soil, and when established—this being facilitated by keeping rather close and shaded for a few days—shift into the fruiting pots. You will then secure, under good management, canes of the length and strength desired for bearing in pots the succeeding season.

Madresfield Court Vine not Growing (Idem).—We are not surprised at the Vine placed in a space of only 2 feet square not growing satisfactorily, as the roots could hardly have been spread out at planting and given a chance of taking proper hold of the soil. Of course there may be other reasons for the Vine not thriving, such as overwatering and destroying the roots, or, on the other hand, keeping too dry, so that growth cannot possibly take place. In the absence of particulars we cannot otherwise account for the lack of progress. Perhaps it has been injured in some way, or sufficient time not allowed for it to start into growth.

Tennis Lawn (J. V. H.).—There is no orthodox size for a lawn tennis ground, but it should not be less than twice the length of the width of the net, which is usually 36 feet or 42 feet wide, and it is better to have too much rather than too little room: hence 30 yards and 18 or 20 yards wide is preferable to a lawn only just large enough, looking much better and being pleasanter for all concerned. A full-sized tennis "court" is 78 feet long and 36 feet wide.

Winter Salading (G. W.).—As there is a difficulty in obtaining Lettuce with good white hearts during the months of February and March, we should advise you to rely upon blanched Endive during that period, and Chicory, which are admirable winter salads. Endive may be readily blanched by tying up the tops of the leaves, and inverting a pot over the plant, stopping the hole with a stone. A slate laid flat on the plants is a method adopted by some, and answers well. Chicory is readily forced in darkness and heat.

Soft Rot in Celery (W. S.).—The "head" has the central part decayed, and brown or black. It is what is termed "soft rot," and by some regarded as due to bacterial agency, but we failed to discover any micro-organisms of that nature in your specimen, or any form of life of a fungoid character. A small portion of the decayed part swarmed with eelworm, commonly called stem-eelworm, *Tylenchus devastatrix*, also innumerable eggs of the eelworm. We do not consider the eelworm the cause of the "soft rot," but rather as the consequence of the decay set up by excessive moisture in the heart of the head of Celery, and the cause of that decay we should attribute to the sewage. The eelworms may have been aided by the soft character of the central stalks, and thus have pierced them and furthered, if not produced, the rot, for it is difficult in such cases to separate or distinguish cause from effect. White Celeries are no more tender than red varieties, yet not all, for Sandringham is one of the very best for late use. We should give the land a good liming, say half hundredweight per rod, and point in shortly after slaking, then supply a top-dressing of kainit, $3\frac{1}{2}$ lbs. per rod, and leave for the rains to wash in.

Diseased French Beans, Cucumber, and Tomato Plants (J. and S.).—The whole of the plants are "cankered" at the roots and more or less in the root stems, and in these are the threads of a fungus, *Fusarium lycopersici*, which is popularly known as "sleepy disease." The plants collapse or "blister" in the leaves under powerful sun because their feeding roots are destroyed, hence not able to supply sap in proportion to the water evaporated from the leaves. We failed to detect any trace of animal pests at the roots or in the soil, though we subjected all the samples to careful microscopical examination. The soil is practically devoid of lime, and to this may probably be due the presence of the fungus. We should supply a dressing of best chalk lime, preferably air-slaked, using half a pound per square yard, and where possible pointing in lightly with a fork. In the case of soil for potting or beds we advise $2\frac{1}{2}$ per cent. of the lime named to be mixed with it, and some little time before use, turning once or twice to insure even incorporation; or, as equally effective, and at the same time supplying both lime and phosphoric acid, basic slag phosphate, 1 lb. per square yard, pointing in as advised for the lime. For mixing with soil use 7 lbs. of basic slag phosphate per cubic yard, incorporating thoroughly. Either lime or basic slag phosphate would be likely to give the desired relief, and the soil would be further improved by an addition of wood ashes; or kainit may be used in the proportion of 2 to 3 ozs. per square yard for top-dressing. The soil also appears deficient in grit, and would be improved by the addition of one-sixth of old mortar rubbish. We cannot analyse in any case, hence express no opinion on the water; but as this does not act prejudicially, or appear to do so only under the influence of powerful sun, we can hardly consider injury to arise from its use. If you want an analysis it may be had for a reduced fee from Dr. Voelcker through Royal Horticultural Society if you are Fellows.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (C. F. P.).—1, *Linum flavum*; 2, *Freesia Leichtlini*; 3, *Cypripedium superbiens*; 4, *C. barbatum*. (A. L. B.).—1, *Maranta Veitchii*; 2, *Adiantum trapeziforme*; 3, *Ficus repens*; 4, *Veltheimia viridifolia*; 5, *Lachenalia Nelsoni*; 6, *L. pendula aureliana*. (J. G. T.).—1, *Adiantum pubescens*; 2, *Asplenium flaccidum*; 3, *Cattleya Trianae*. (H. M. C.).—1, *Dendrobium nobile*, fine dark form; 2, *Cypripedium insigne*; 3, *C. superbiens*; 4, *Pteris argentea*; 5, *Polystichum capensis*. (H. S. E.).—1, *Cupressus Lawsoniana*; 2, *C. L. erecta viridis*; 3, *Thuopsis borealis*; 4, *Retinospora ericoides*. (Park Hill).—*Cupressus punebri*. (Interested).—The Anemone is Rose de Nice, which can be procured from most seedsmen of repute. (W. B.).—The Ayle is Dumelow's Seedling, slightly malformed. (P. C.).—1, *Prunus sinensis flore-pleno*; 2, *Boussingaultia basseloides*; 3, *Deutzia gracilis*; 4, *Crassula lactea*; 5, *Veltheimia viridifolia*; 6, *Angræcum sesquipedale*.

SMALL PROPRIETORS.

VERY small indeed, and a vast number of them, all very hard working and industrious, and very agricultural. This land is not within the confines of Great Britain, but is over seas; near enough to be counted as our neighbour, and near enough for us to learn something of the methods of this most methodical people.

If we have not visited Belgium in actual bodily form, we have been taken there in spirit by several of the writers to this our good old Journal. Our friends have gone, not so much to view Belgium from an agricultural as from a horticultural point of view. They have told us much of interest, and much that has made us inclined to be a bit shame-faced. They are such thorough energetic workers, and mean so to get on. Did we not read of one of the gardeners interviewed who learnt English that he might read in the original the collected wisdom to be found in our pages? Yes, we feel sure it was. And can we point to many English working gardeners who have taken up the study of French or German so that they might read gardening journals in those tongues?

We have just looked up a few facts about Belgium. The area is 11,373 miles, with a population of something over 7,000,000. We find exports run somewhat thus—Yams, £6,617,400; cereals and flour, £6,614,760; machinery, £4,324,400; with an annual output of over 20,000,000 tons of coal. Pretty good for so small a country, but what we want to be at is the manner by which they work the land so as to allow of nearly £7,000,000 of agricultural produce. It can only be arrived at by what may properly be termed intense culture and spade husbandry. We are not going to compare the relative position of the agriculturists themselves—viz., English working farmers and their Belgian brothers, for we know full well that no Englishman could or would exist on the pittance that contents the foreigner; nor would he with his wife and children endure such hard and continuous toil.

We English cannot quite grasp the idea of the smallness of the Belgian farms; in fact we should hardly call them farms, rather allotments. The average size of the farm is $7\frac{1}{2}$ acres, but in one district there are 22,000 acres divided into 6328 farms, thus making the farms not more than 4 acres apiece. Only a quarter of this land is pasture, and the number of cows kept is 2990, and horses 744. The cows cannot have a very wide range of cow pasture, but must be kept entirely in stalls save when allowed to graze, well watched, by the roadside. A cow requires an enormous bulk of food, be the quality what it may, and this food has all to be cultivated. We mean this in contradistinction to grass land which may have been laid down for generations.

We wonder how many of these holdings are required to sustain a horse. He must be a co-operative horse, and we wonder how his many masters contrive to divide his services. We fancy there must be a good deal of spade labour, no waste in fences, and little in occupation roads. How tiny the plots must be, and how clean. These people help themselves, and also receive much valuable assistance from Government.

As long as fifty years ago the Government organised a number of agricultural societies, who in return for certain money grants gave in an annual report information respecting the state of agriculture in their districts. These societies promote exhibitions, encourage experimental work, and disseminate agricultural literature and foster a spirit of co-operation. About the experimental work there is one very good feature. These small farmers undertake certain experiments in manuring, and in cultivating new or improved varieties of seed; and they receive pay in proportion to the trouble they take. They work out their own salvation as it were, and receive rewards into the bargain.

There is a farm society of Heryele, which consists of 6000 farms, and these farmers are expected individually to do something in the way of experiment for the benefit of the community. They have become quite *au fait* in the region of fertilisers, and fully appreciate the value of new and improved seeds, of careful cultivation and harvesting; and this is done, not by men who have had the advantages of leisure and college courses, but by men who literally earn their bread in the sweat of their brow, for it must be collar work all the year round to get a living off $4\frac{1}{2}$ acres of ground.

Of course we find co-operative creameries. With this class of farms we could expect no other, and as an adjunct to this is established a society to encourage the best milker—i.e. the cow who produces the best quality of milk. There are cows and cows, and where a man has only one or two, he wants them to be super-excellent.

Then comes the help afforded by the credit banks. Then there is a peasants' league of 17,000 members, who purchase feeding stuffs and manures, and who have seventy credit banks, with deposits amounting to over £20,000. Then, again, we find stock insurance companies a little on the lines of our pig and cow clubs. The premiums are not extravagant— $1\frac{1}{2}$ d. per month on £4 value—so that every class of animal comes under the schedule.

They do not stop at cattle insurance, but go on to fire risks, and

have made excellent terms with some existing companies. They do not miss a point, these good Belgians; they are alive to their difficulties, and they are also fully prepared to meet and overcome them.

They have not a big country, nor one that is by nature very fertile, but by constant labour, and that of the best (self-interested), they make it a veritable Garden of Eden. A farm of 4 or even 7 acres extent is not beyond the purchasing powers of a working man, and we expect it is this hope of ultimate possession that makes the farmer rise early and toil late.

There is something fascinating about the possession of land; even the ownership of a little field makes us feel we have a stake in the country—a tangible something.

WORK ON THE HOME FARM.

With the advent of March with its high winds and the land in more suitable condition, farmers will everywhere be thinking of sowing Barley; but what Barley are they to sow? This is a very important question, and one not easy to answer. Generally speaking, we should say that the use of newly selected seed in no case shows such satisfactory results as in the case of Barley. To attain perfection for malting purposes every grain should be as like its neighbour as peas from one pod. Wheat and Oats are different, for though fresh seeds may be desirable as increasing the quantity of produce, the quality is not very highly affected.

What is more important than anything in selecting seed Barley is in having it free from smut. We see people recommending the dressing of smutted seed with blue vitriol. We say do not use such seed at all. We have ourselves done so, and although the seed was doubly and carefully dressed, the crop was heavily smutted.

Get the cleanest seed you can, and then dress it with vitriol. We believe in this dressing, but a badly smutted stock takes years to cure. Prevention is the best policy, so use clean seed and use preventive measures.

Some Barleys are much more liable to smut than others, Goldthorpe and Standwell particularly so, and great care must be exercised in selecting stocks of these varieties. Pedigree stocks are almost always clear of smut for a time, and if one considers that 1 qr. at 20s. will sow 4 acres, the extra outlay on a crop of 5 qrs. per acre only amounting to 2s. 6d. per qr., and that this will be reduced in the next year's crop to about 2d. per qr., the great advantage of a yearly purchase of pedigree seeds will be fully apparent.

We are thrashing again, and the weather is very favourable, being fine and dry. We are fully occupied with cross-cutting fallows, and the land is turning up in very nice condition, drier than we had expected. With a continuance of dry weather we shall be able to drag and harrow and complete the fallowing and cleansing process; fortunately the fine autumn left little to do. Prices do not mend, everything is low—grain, Potatoes, and meat.

MR. ROBERT SYDENHAM'S LISTS

Are acknowledged by all to be the Best, Cheapest, and Most Reliable ever published. They contain only the Best Vegetables, Flowers, and Bulbs worth Growing, being the Selections of the Largest Seed Growers, Market Gardeners, and the Most Celebrated Professional Gardeners and Amateurs in the Kingdom. They also contain very useful Cultural Instructions.

Mr. SYDENHAM'S Bulbs and Seeds were represented and gained First Prizes at London, Birmingham, Preston, Newcastle-on-Tyne, Shrewsbury, Edinburgh, &c., &c., in 1892, 1893, 1894, 1895, 1896, 1897, and 1898.

SWEET PEAS A SPECIALITY,

At a Third or a Fourth Usual Prices.

Nothing gives so much Cut Bloom at so small a cost or so little trouble. To get best results SOW AT ONCE, as directions sent with each Collection.

SPECIAL VERY CHEAP OFFER.

COLLECTION No. 1.—Ten Very Good Varieties.

50 Seeds of each in separate packets, 1s. 3d.

Emily Henderson, white; Blanche Ferry, pink and white; Mrs. Eckford, primrose; Royal Robe, pale pink; Splendour, rich deep rose; Firefly, rich bright carmine; Meteor, salmon and pink; Emily Eckford, bright pale blue; Countess of Radnor, pale heliotrope; Monarch, dark bronzy-purple.

COLLECTION No. 2.—Ten Very Choice Varieties.

50 Seeds of each in separate packets, 1s. 9d.

Blanche Burpee, finest white; Queen Victoria, pale yellow; Venus, pale lemon-pink; Lovely, delicate pink; Her Majesty, soft rosy pink; Lady Penzance, bright pale rose; Mars, intense glowing cardinal; New Countess, fine pale heliotrope; Countess of Powis, orange-salmon and pale pink; Stanley, large bronzy-purple, the best dark Sweet Pea.

Special Price for the Two Collections, 2/6 Post Free, with a packet each of White and Pink Cupid (25 Seeds) FREE OF CHARGE.

COLLECTION No. 3.—Ten Newest Varieties.

50 Seeds of each in separate packets, 3s.

Sensation, blush white; Modesty, blush pink; Prima Donna, large pink; Lottie Hutchins, buff, flushed pink; Oriental, bright rose; Triumph, salmon and pink; Gorgeous, orange and pink; Captivation, rosy-purple; Colonist, lilac-rose; Salopian, deep mulberry-red.

Special Price for the Three Collections, 5/-, with a packet (25 seeds) of Pink and White Cupid, and four striped varieties (50 seeds of each) FREE OF CHARGE.

All Seeds are warranted New Seed of 1898 Crop and carefully hand-picked, all small and doubtful Seeds being taken out.

THE BEST SIX TOMATOES

In cultivation; often sold under other names to get fancy prices. Each packet contains about 200 seeds. Perfection, 3d.; a special good strain, Ham Green Favourite, 3d.; Roseleigh Gem, 3d.; a grand new selection, large smooth, Challenger, 3d.; Golden Perfection, 3d.; EARLY OPEN-AIR, the best for outdoor work, 3d. Collection, 1s. 3d., post free. If ordered separately, 1d. each extra for postage.

THE FOUR BEST CUCUMBERS.

Each packet contains 10 seeds. Lockie's Perfection, Rollison's Selected Telegraph, Covent Garden Favourite, and Marvel, 6d. each; postage 1d. each extra; or the Collection, 2s. post free.

VOICES OF THE PAST.

IT has been said of old "the world knows nothing of its greatest men," and similarly it might be asserted that the world knows nothing of its greatest gardeners. There were brave men before Agamemnon and poets before Homer. The world makes its heroes out of those whom circumstances have contributed to advertise at populous centres, while there have always been modest inglorious savants hidden away in quiet villages and suffered by the all-pervading press to lead a placid life in pursuit of the real pleasure of self-development.

It is to these great unknowns of past ages, the rule-of-thumb men, who, inheriting from their predecessors an accumulated fund of experience, have handed it down to us with something superadded of their own, that our gratitude is due. They laid the foundations upon which the imposing edifice of modern scientific literature is based.

Thus the old workers and old writers have a strong claim to our gratitude. We are too thankful for all they have taught us to employ ourselves in pointing out their deficiencies. Moreover, we feel that if they were living and teaching in our times, they would give very different series of instructions from those which have, nevertheless, been so useful. Let us also remember that many, if not most, of the old writers on gardening were not specially equipped by scholastic acquirements, but rather grounded in practical work and fitted by self-improvement for advocating the extension and the advancement of horticulture. Such men—practical gardeners—laid the foundation and commenced the superstructure of British gardening.

Of the present century gardeners we may remark that they received considerable assistance in obtaining information and in disseminating practical knowledge, from the garden and the "Transactions" of the Horticultural Society of London. This, however, represented the classes rather than the masses. It is to London's "Gardeners' Magazine" that the palm must really be awarded for initiating gardeners into the sound all-round practical principles of garden literature. Then in 1841 came the "Gardeners' Chronicle," a weekly journal on

horticultural and agricultural subjects, which pursued and yet follows a course that may be said, in the highest sense, to embody science with practice. Still there were left vast numbers of individuals who considered themselves uncatered for by the gardening press, or found that press from its costliness to be beyond their reach. To supply this deficiency in horticultural matters the *Cottage Gardener* was founded by the late Mr. G. W. Johnson, and the first number appeared on October 5th, 1848.

Going back to the first issue of the *Cottage Gardener*, we read, in the introductory chapter, that its prime object was *utility*, for the gardener, amateur, and cottager, who, severally, desired instruction "how to grow the most and the best crops." In order to effect these results *notice* would, from time to time, be made of the "varieties distinguished for qualities most desirable, modes of culture found to be most successful, most appropriate manures, with modes of applying them most economically, and rotation of crops found advantageous on various soils." Particular attention would also be paid to the diseases of cultivated plants, and to the insects which attack them, with advice on their eradication and extirpation. Plans of gardens were also promised, with notes on their arrangement.

"To enable us to attain these objects," says the Editor of the *Cottage Gardener*, "we have secured the aid of some of the best practical men of the day, and to facilitate their labours we solicit assistance from all others of like acquirements, whether professional or amateurs; but, in all we examine and all we recommend, experience shall be our touchstone."

"No one values the services of science more highly than we do. We well know that it points out and illumines the path of the gardener; it aids and sustains him in his progress along that path—but the path itself is Practice. Upon this we shall place our foundation."

Thus wrote the founder of the *Cottage Gardener*, and every reader of its twenty-five volumes knows how truly the works reflected the words. The *Cottage Gardener* began its career without a motto, but it was clearly expressed in the introductory chapter, and manifested in every line of the articles, bearing as they did the stamp of *Practice* linked with *Science*. When upon attaining its thirteenth year the familiar title of *The Cottage Gardener* became subordinated to that now consecrated by more than a generation of time, the readers of the *Journal of Horticulture* suffered no loss. The transfiguration of name touched not its spirit, for with the *Journal of Horticulture*, as with the old *Cottage Gardener*, "Practice and Science" remains, and ever will remain, the abiding watchword.

Turn we now to the writers of the *Cottage Gardener* and *Journal of Horticulture*, "who, being dead, yet speaketh."

ROBERT ERRINGTON.

After the introductory remarks of the Editor the first article was from the pen of Mr. Errington (fig. 35). It was entitled, "The Week's Fruit Gardening," and the opening sentences clearly defined the scope of the teaching—"sound gardening practice, adapted to all who cultivate a garden." "Scientific terms," he says, "would be abstained from as much as possible," and "a plain style" be adopted, so as to render the subject familiar to the humblest cottager. Truly this contributor's articles are characterised by plain, trenchant Saxon and by sound knowledge of the subject in hand, as befitted a practitioner of "some forty years' experience."

Fruit gardening was Mr. Errington's particular *forte*; but, as might be expected, he had kitchen gardening in heart, head, and hand, hence numerous articles appeared from his pen on diversified subjects. On December 20th, 1854, we find him advertizing to the Potato disease as less malignant, and to the benefits to the working man of a cheap loaf. Thus humanity had a place in his large heart as well as the adornment of the pleasure ground and the forcing of fruits for the opulent. As an all-round cultivator freely giving of his bounteous experience he had few equals, and certainly no superior in knowledge.

THOMAS APPLEBY.

The second article was written by Mr. Appleby, who, in his opening statements, says "the culture of flowers is one of the most delightful and beautiful recreations to which man can devote the powers of his mind and body." Having, he tells us, tasted these pleasures for nearly half a century, the aim will be "to increase the taste and instruct the ignorant . . . make the culture of flowers

more general and the practice more easy," and thus have the satisfaction of "a mite cast into the treasury of human happiness."

Mr. Appleby treated of the flower garden in a clear, simple style, but in florists' flowers settled down into plain instructions. In these, and plant culture generally, both outdoor and under glass, he displayed considerable talent and inherent love of the beautiful. He told of all that was worth growing, and of everything in matters of culture that could be helpful and was essential to success. From

FIG. 35.—MR. ROBERT ERRINGTON.

specialities the writer passed into what may be termed generalities, such as "woodcraft," or the cultivation of trees and shrubs, growing Vines and Pine Apples.

JAS. BARNES.

No flourish of trumpets heralds the advent of Mr. Barnes into the arena, but every reader recognised the contributor to "London's Gardeners' Magazine" as a proved hand, and "good wine needs no bush." Very plain were his instructions about Borecole and Brussels Sprouts, even planting in October to have "heads and sprouts" in spring. The remarks on planting Potatoes in autumn, because for several previous years "the autumn-planted have been the only Potatoes of good quality and abundant in produce," were incisive. Experience and hard-headed practice are the dominant features of "Barnes of Bicton's" writing. Not that he was devoid of science, for a more practice-with-science article on the "Management of Soil" has not, perhaps, been given in less space, and yet more exhaustively on essential points, than his on page 7 of the first number of the *Cottage Gardener*. As a kitchen gardener Mr. Barnes was unrivalled, and was one of the "lights" of his time. He strove to secure abundance of food to the community, and, by mutual dependence and inter-communication, comfort to the cultivator. As indicative of the store set by vegetable growing, we may mention that the earliest probe given the contributors for information was by "Nemo," who wanted to know, and was told how to preserve his seedling Cauliflowers from the attacks of slugs. Then, as now, it was the "good old plan" of advising something hurtful to the pests, but harmless, and, better, profitable to the plant and culture. This was a predominant characteristic of this writer—make the soil right, then there will be a chance, not otherwise, of its producing healthy and full crops.

CUTHBERT W. JOHNSON, F.R.S.

This man of science, whose enthusiastic efforts in the cause of practical sanitation have conduced to the health and life of thousands, took "Filtered House Sewage" as his theme. The name suffices for the utility of the article cast upon such sound practical lines. Indeed, everything in the first issue of *The Cottage Gardener* was founded upon the broad principles of "prove all things"—the voice of the scientific as well as that of the practical man. Thus we find in all the issues of the publication from 1848 until 1899 practice combined with science. Of the voices that spoke in the initial

number none abides in the flesh, but now they are heard and remembered through their works with feelings of thankfulness.

DONALD BEATON.

Donald Beaton entered the list of contributors exactly a month subsequent to the paper's inception, which then necessitated a double number (sixteen pages instead of eight) "without extra charge." His task was "The Week's Window and Greenhouse Gardening," in which he secured his readers' confidence by bestowing praise where credit was due. "The cottager," he says, "who can manage to grow half a dozen of pot plants in his window—flower them well in summer, and keep them safe through the winter—may be said to be so far a good gardener." This encomium from such a source was music to the cottager's ears, which he knew or learned how to tingle so as to awaken and maintain interest. There does not appear, in his first article devoted to "Window Plants" anything of the botanist, the geographer, the hybridiser, or the experimenter—no, not even so much as that of the great gardener; but it teems with cogent reasons for avoiding this and doing that.

In his next contribution the habiliments of orthodoxy are discarded, and Mr. Beaton appears in his true racy character. He tells a tale about "a hobby-horse" which, "if fresh, is almost as difficult to manage at first as an Arab steed fresh from grass—the restlessness at starting is much the same with both, and each requires some time and management before he can be made to take to the road straight forward. But you will probably ask—What has that to do with gardening and pot plants? Very little I own. The subject, however, that is, giving directions in gardening to new beginners, is one of my hobbies, and in starting with it fresh last week it would take any direction but the straightforward course."

To name Donald Beaton amid gardeners draws forth needs of praise, hence his portrait will be peculiarly acceptable. Who has not profited by his writings? His forte was flowers—in the garden, window, and glass house. Who did not know, or had not heard of, the canny Scot, with his "hobbies" in giving directions to beginners, with rare talent of criticism, with genius adapted to increasing and improving plants and flowers, and with great power of invective exercised to inculcate sound principles, and to lead from "rule of thumb" into a better system of procedure?

We have given a brief retrospect of the departmental writers that illumined the first volume of the *Cottage Gardener*. None of those now to be considered had, so far as we know, any part therein, and we shall take them in the order of utility recognised by the founder of the paper—namely, fruit and forcing garden, kitchen garden, flower garden, florists' flowers, greenhouse and window garden, not however separating their work in other departments from that in which they shone brightest.

ROBERT HOGG, LL.D.

In a very valuable monograph of "The Garden Pea and its Varieties," Dr. then Mr., Hogg, adverts to the size of seedsmen's catalogues, and asks, "Have they done so to the same extent in utility?" Of course this refers to varieties of Peas, which then (January 20th, 1854), as now, were so multiplied in name as to lead to "nothing but confusion, disappointment, and annoyance." The monograph, illustrated by outline representations of the many varieties regarded as distinct, is a masterpiece of erudition, yet so plain in style and simple in words as to be easily comprehended.

Of Dr. Hogg's contributions on fruit culture it is needless to make any remark, they are too well known. His contemporaries who worked with him knew his worth, but posterity will estimate him by the work he did and the legacy he left to pomologists in "The Fruit Manual." It remains a memorial of one "head and shoulders above his fellows" in fruit classification, description, and knowledge.

THOMAS RIVERS.

The Sawbridgeworth nurseries have long been famous for Roses and fruits. The first were unquestionably Mr. Rivers' first love, as attested by "The Rose Amateur's Guide," published in 1837, and reached its fourth edition in 1846. This was solid testimony to the value of the book as tending to increase and improve the national flower. But fruits were very dear to his heart too, for he lovingly refers to trees of his boyhood days—to Pears, to Apples, to Nuts, to every kind of fruit in which youth delights. They did not quite satisfy him, however, good as they were; he longed for, and set to work to achieve their advancement by improved methods of cultivation and by Nature's plan of evolution—cross fertilisation.

Enthusiastic, methodical, "every inch a gardener"—and ever as he advanced going hand in hand with science—he accomplished more towards producing new and better varieties of fruit in a lifetime than had been effected by trusting to Nature and acting upon the principle of selection alone during centuries. In Apples, Apricots, Cherries, Cob Nuts and Filberts, Figs, Nectarines, Peaches, Pears, Plums, and Strawberries he left the impress of his genius, and many varieties bear the

name in prefix of their gifted author, who accomplished so much, through patient, plodding, persevering industry.

Mr. Rivers (fig. 38) was father of the dwarfing system of fruit culture, the trees being more under control and better adapted to both small gardens and commercial culture. He was also the founder of the orchard house, for though fruit trees had been grown in pots anterior to his time he first elevated the plan into a definite method, and showed the way to an "orchard" under glass—dwarf trees in a house, specially and economically constructed, entirely devoted to them.

J. ROYSTON PEARSON.

In the days of this contributor Chilwell Nurseries, Nottingham, were renowned for fruit trees. Mr. Pearson (fig. 37) wrote on Apricots in glass sheds, giving an impetus to glazed projecting copings for walls. He also wrote on orchard houses, advising those plain, light and well ventilated, as opposed to houses of indifferent material and bad construction. Vines, always considered the queen of fruits and most exacting of the gardener's skill to have perfect in colour and finish, was another of his subjects. Though one of the advanced in science his efforts were ever directed to utility—to training trees in the most useful forms, while scrupulously retaining their symmetry and beauty; to originating varieties of fruits distinct from and better in some way than those existing; to improving methods of cultivation, and having great regard for stable or farmyard manure, especially as a mulch for fruit trees. In very clear style he descanted on orchards, had a strong partiality to a grassy bed for standard trees, and pointed out that grazing, not hay culture, was the proper method. Furthermore, he advocated a dressing of animal manure, which he considered lost little or nothing by exposure on the earth's surface, and provided what all fruit trees needed—namely, a steady supply of food derived, as in Nature, from organic sources. Not that he was averse to artificial manures as supplementary to stable or farmyard manure, for he was strong in science, though stronger in practice.

THE REV. C. P. PEACH.

The spiritual and temporal guide of the inhabitants of Appleton-le-Street was a light in pomology and general horticulture, and shone brilliantly, and, better, usefully in the pages of the *Journal of Horticulture* by his writings. He chiefly wrote on fruit culture.

FIG. 36.—MR. DONALD BEATON.

His instructions with illustrations on grafting Apples and Pears are very interesting, and withal profitable. Experience with different varieties of fruits, their doings under varied circumstances, and the influences of stocks, soils, manures, and modes of pruning, were items entering into his treasured articles. On Roses, needless to say, he was great; indeed, no member of the vegetable world was too small or any too large for his great mind, provided there was utility in it.

* We are well aware of its being introduced into England by William III. but Rivers made it a plantation method.

HENRY BAILEY.

Who has not heard of and tasted Bailey's Melons? Few may remember his short pithy articles as "H. B." on the "Orchards of Kent" in *The Cottage Gardener*, but some will never forget his lucid contributions to the *Journal of Horticulture* on "Fruit Tree Pruning" when gardener at Nuneham Park. We say lucid with emphasis, for the illustrations clearly conveyed the directions a multitude of words never do. Fewer and more to the purpose were

FIG. 37.—MR. J. ROYSTON PEARSON.

never employed by any horticultural writer than by Mr. Bailey. True, his contributions were not numerous, but so far as they went they excelled in pithiness and clearness.

THOMAS WEAVER.

As gardener to the Warden of Winchester College, Mr. Weaver may not have been, as measured by extent of charge, a great man, but he certainly was a good practitioner, otherwise he could not have given satisfaction to his employer or employers for a lifetime, or contributed articles during many years. He had the rare faculty of brevity, using short pregnant sentences, ever to the point, and indicating hard-headed principles guided by horny-handed practice. His instructions for the kitchen garden bore the stamp of the "man of mark," working hard on well defined lines. They still abide as landmarks of what must be done in the vegetable garden day by day, week by week, and month by month, in order to maintain a constant supply of vegetables and salads throughout the year.

JOHN ROBSON.

What? A kitchen gardener! Yes, verily, Mr. Robson began his gardening career as kitchen server. Hence he entered upon his writing life fortified with the hand and head work essential to keeping all things smooth in the kitchen, while making everything pleasant and satisfactory in the dining room. In the kitchen garden the kid-gloved hands do not shine in work, except on necessarily tender-handed amateurs, and they, as a rule, write best that have done most by hand and head. Mark, "most" means greatest or highest degree—the gardener using every available means to render his charge attractive and satisfactory. The cottager's garden, an allotment, or any small space of ground, has as much claim to *not* as the garden or field measuring acres, for the union of labour with intelligence can be shown as well upon a small as upon a large scale.

But John Robson excelled in fruit gardening as well. Great as he was in the kitchen or fruit garden, he was greater in the pleasure grounds, and amongst broad and narrow leaved trees, flowering and leafy shrubs, plants of many kinds, and every species or variety in its proper place. An arboriculturist of the first order, pleasure ground director of the front rank, and flower gardener of the foremost, Robson's "hobby horse" was plans of flower gardens, how to prepare the beds, what to plant, the way to manage, and make a place beautiful at all seasons.

JOHN WILLS.

Decorative art was natural to Mr. Wills. Flower gardening in private establishments could not contain him, or hybridisation or increasing and improving plants and flowers by cross-fertilisation satisfy his ambition; hence he strove for and secured "fresh fields and pastures new." The great metropolis of the world alone did not

afford scope for his operations, but he must needs initiate and control one of the greatest businesses the world has yet seen in decorative art. The flower girl, the plantsman and florist, the wreath maker and bouquetière, the horticultural builder and light goods transporter—every lover of flowers, all those who delighted in adorning their houses with plants and flowers, everyone seeking to solace the sick and pay tributes to the departed, have reason to respect the master of the art of floral decoration—John Wills. He wrote fluently, and ennobled the craft by his efforts to adorn mankind and homes in garniture superior to that of "Solomon in all his glory."

THE REV. W. F. RADCLIFFE.

The Rector of Rushton was famous for the cultivation of the queen of flowers—the Rose—loved it in the garden, against the walls of English homes, and in the greenhouse. Its perfume was to him the nectar of the gods; its form and its tints of colour the rainbow of enduring love. He wrote, as only the educated can, so that all willing ears understood and profited. At Okeford Fitzpaine he directed his attention to fruits, especially Peaches and Nectarines on low walls. In the articles on these and kindred subjects the gardener appeared very conspicuously, his hobbies, like Mr. Beaton's, being to give plain directions to beginners, useful help and sound advice.

THE REV. A. HEADLEY.

The Rector of Hardenhuish was a self-taught rosarian, who had no teacher but the *Journal*, and the God-given love of Nature. His writings, ever overflowing in humanity, endeared all hearts to him, and, knowing this, longed for weekly intercourse with kindred spirits, and found no difficulty, through "Our Journal," in securing it. To say that his writings adorned these pages is not enough—he worked to increase and improve the produce of the land in beauties inculcated by the undying love of Nature.

ROBERT FISH.

At Putteridge Bury, Mr. Fish was famous in flower gardening—nay, in every department. "Very particular" was his predominant characteristic—as to soil, handling and smelling to ascertain texture and sweetness. Yes, he was "very particular." In writing more than that, for was he not always exact? "Hobbies," he had none, all requirements of the cottage, the villa, the mansion, for plants, flowers, fruits, and vegetables were one to him. If the dwellers wanted those things they must have them from their gardens. What he did in this direction was a delight to him to impart to others. To help anyone in difficulties was a duty—gardening must succeed. What he performed in work of this nature may be found in the files of the *Cottage Gardener and Journal of Horticulture*. No one laboured more, few so well, and none better to make all men gardeners. This great Scottish gardener ranks as one of the most useful writers on British gardening, and no name amongst gardeners in the United Kingdom stands before his as an all-round gardener.

WILLIAM KEANE.

This name appeared continuously for many years, and Mr. Keane's style differs from that of all other writers, but somewhat resembled Mr. Weaver's in shortness of sentences, and in placing a great deal in little space. Unlike that very practical gardener, however, he could enlarge on almost any subject, but he seldom did more than the calendar. "Work for the Week," so far as it was written by him, evidences sound knowledge on the several departments of gardening, his directions being explicit and calculated to meet the requirements of all classes of gardeners.

Many other names of horticultural writers in the *Cottage Gardener and Journal of Horticulture* occur to us, and also those that have enriched the pages on allied subjects, such as Mr. H. W. Newman on natural history, Prof. Westwood on insect pests, the Rev. M. J. Berkeley on diseases caused by fungi and other micro-organisms, and Mr. H. Honeyman on chemistry, with the Rev. W. W. Wingfield on poultry, Mr. J. H. Payne on apiculture, and Mr. J. Blundell in the "Home Farmer." The line of exclusion must be drawn, and in doing that we refer all interested to our files, wherein will be found *men of mark* not less noteworthy in some respects than those of whom we have endeavoured to give some account, and of whose works there can be no question as regards utility. This is the measure by which all men abide in history, and thus they do in the annals of the *Journal of Horticulture*.

THE VETERANS' PORTRAIT GALLERY.

From those whose voices are hushed in death we must turn to writers who are a host in themselves at the present day. Portraits of these have been distributed throughout the succeeding pages, each being accompanied by an article on some congenial subject. It is to such men that readers of the *Journal of Horticulture* have looked for

interest and, be it understood, for instruction, and not in vain. Their facile pens and well trained minds have ever been at the service of our readers, and it is as a small tribute of respect that their portraits are reproduced. Several of them will be personally unknown to the majority of the *clientèle* of "our Journal," and this may be given as justification, if such be needed, for the introduction of "The Veterans' Portrait Gallery."

We may briefly look at their record in connection with the *Journal of Horticulture*. Priority must be accorded to Mr. Robert Fenn, whose pseudonym of "Upwards and Onwards" was sufficient guarantee for sound common sense. Then the Rev. H. Honeywood D'Ombraïn, as "D., Deal," has been known for forty years as the king of florists, and his articles are always read with the keenest interest by everyone. From the remainder included within this academy of horticulturists, it would be invidious to give one precedence, as each has contributed for periods ranging from thirty to thirty-five years. The Rev. C. H. Bulmer, as "Herefordshire Incumbent," has done yeoman's service in the Rose world, both in and out of these pages, as also have Mr. Wm. Paul and the Rev. Alan Cheales. As a writer on cultural topics, embracing all phases of gardening, Mr. Edward Luckhurst will be well known to this and the last generation. Than Mr. N. H. Pownall none has written more entertainingly and withal instructively, but he has largely cloaked his personality by the *nom de plume* of "An Old Provincial." Of insects that are friendly and unfriendly to gardeners, "Entomologist" has related in pleasant style; such was the cognomen of Mr. J. R. S. Clifford, who also told of the garden lore of London and its environs as "J. R. S. C." As a demonstrator of the practical culture of flowers, fruits, and vegetables, Mr. Jas. Douglas has made his name widely known and universally respected. Is it necessary to refer to the works of Mr. George Abbey? Assuredly not! They are

FIG. 38.—MR. THOS. RIVERS.

now and will ever remain tributes to the man whose pride lies in work well done, whether he were treating of insect pests, fungoid diseases, or the growth of plant life.

There are others in addition to those named who have laboured in the field of gardening as represented by the *Cottage Gardener and Journal of Horticulture*, but facilities do not enable us to give them deserved publicity. Younger writers have done their duty, and they, when the century of "Our Journal" is come, will occupy no less exalted positions, in their respective spheres, gained by services rendered "For Gardening and Gardeners."

RECENT WEATHER IN LONDON.—Wintry conditions, so far as cold winds and sharp night frosts are concerned, continue to prevail. Each morning brings fog and frost, followed by brilliant sunshine later in the day. On Saturday there was a slight hailstorm, with a cold shower later in the day. At the time of going to press on Wednesday it was bright and warm.

WEATHER IN THE NORTH.—February closed with two days of moderate frost in the earlier parts, thaw setting in later on the 28th ult. March has so far been marked by high winds from the west and north. On Sunday morning 2 inches of snow covered the ground, and it continued to fall heavily till midday, when rain set in. By Monday morning the snow had almost disappeared from the low grounds, that day being very wet in the former part, with a dry and cold afternoon.—B. D., S. *Perthshire*.

ROYAL HORTICULTURAL SOCIETY.—The next Fruit and Floral meeting of the Royal Horticultural Society will be held on Tuesday, March 14th, in the Drill Hall, James Street, Westminster, 1 to 4 P.M. A lecture will be given at 3 o'clock on "The Duke of Bedford's Experiments at Woburn: their Object and Method," by Mr. Spencer Pickering.

ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held at The Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 15th inst., at 7.30 P.M., the following papers will be read:—"The Prolonged Deficiency of Rain in 1897 and 1898," by F. J. Brodie, F.R.Met.Soc.; and "The Climate of Jersey," by the Rev. H. W. Yorke, M.A.

SEAKALE PLANTING.—The thong-like roots cut away from the large clumps when lifting them to prepare for forcing make the best material to increase stock. Cut them into lengths of 6 inches, the upper surface of roots transversely and the lower end slantingly. They should be laid in sand for a time, when it will be found that a ring of growth is formed from which the future shoots originate. These appear so thickly that it is necessary to reduce them in number when they appear above the soil. Place them in rows 2 feet apart, and a foot distance in the rows.—E. D. S.

NAPOLEON'S PALM TREE AT ST. HELENA.—The St. Helena Palm, which was valued so highly by Napoleon I., has been dead for some time. The Emperor often sat in its shade, dreaming of his glorious past. It was Louis Philippe's wish to have this historical tree transferred to the botanical garden at Paris, but the project was never carried out. Now the proud Palm is sold for firewood. With it, says a contemporary, disappears from St. Helena the last remembrance of the Emperor. The house in which he lived is fast crumbling away, and no one thinks of repairing it. The bedroom is used for a pig pen.

NATIONAL AMATEUR GARDENERS' ASSOCIATION (LIVERPOOL BRANCH).—On Thursday a successful meeting was held, the new President (Mr. W. Histed) occupying the chair. The medals and certificates won by members during the past season were distributed. Afterwards the President in a few graceful words asked Mr. R. Pinnington of Roby to accept of a solid silver cigarette case with suitable inscription, as a token of the esteem and friendship entertained for him by all members of the branch. Mr. Pinnington spoke of his connection with the branch, and also the satisfaction it gave him to help them in any way. There were some charming exhibits from Messrs. McGregor, Turner, Drake and Cangle.

ISLE OF WIGHT.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday Dr. J. Groves presided over a good attendance of members from all parts of the Island, who were present to hear a paper read on the "Cultivation of Peaches and Nectarines," by Mr. W. Tribbick, Brooke House Gardens, I.W. The exhibits staged were of first-class quality, and consisted of Cyclamens from Mr. A. J. Cole, Broadlands, Sandown, and flowering and foliage plants from Mr. A. E. Cave, Newport. The Association certificate for cultural merit was awarded to each of the exhibits. Several new members were elected. The exhibition of spring flowers will take place at Ventnor on April 1st.—S. H.

METEOROLOGICAL OBSERVATIONS AT CHISWICK.

Every morning has been more or less foggy, followed later by bright sun. The temperature has been lower than in any previous week during the winter. On Saturday, March 4th, there was a slight hailstorm.

— **SUSSEX RAINFALL.**—The total rainfall at Stonehurst, Ardingley, for February was 3.10 inches, being 0.70 inch above the average. The heaviest fall was 1.82 inch on the 8th. Rain fell on eleven days. The maximum temperature was 56° on the 10th; the minimum 25° on the 28th. Mean maximum, 46.18°; mean minimum, 35.23°. Mean temperature, 40.70°, which is 3.85° above the average. Since the 15th we have had no rain, but have enjoyed thirteen days in succession of bright sunshine, with slight frosts at night.—R. I.

— **FEBRUARY WEATHER AT BELVOIR CASTLE.**—The prevailing direction of the wind was S. on twenty-one days. The total rainfall was 1.19 inch, which fell on twelve days, and is 0.62 inch below the average for the month. The greatest daily fall was 0.31 inch on the 15th. Barometer (corrected and reduced) highest reading 30.637 inches on the 28th at 9 A.M.; lowest reading 28.826 inches on the 13th at 9 P.M. Thermometers: highest in the shade 62° on the 10th, lowest 23° on the 26th and 27th. Mean of daily maxima 47.07°, mean of daily minima 33.25°. Mean temperature of the month 40.16°; lowest on the grass 16° on the 28th, highest in the sun 110° on the 10th. Mean temperature of the earth at 3 feet deep 40.82°. Total sunshine 118 hours 20 min. There were four sunless days.—W. H. DIVERS.

— **PHYSIANTHUS ALBENS.**—Your remarks on the above plant at page 148 induce me to send you a pair of fruits taken from a plant growing outside and trained to a wall over a doorway, where it is always an object of interest, either in summer, when it is covered with its creamy white flowers, or autumn and winter, with its peculiar fruits. Here the plant seems perfectly hardy, and regularly ripens its fruit, at least ripe enough for its seeds to grow, although I have never seen them of an orange colour. Our plant has thirty fruits on it this year.—W. PROSSER, *Moreton House, Dorset*. [The fruits were excellent, and we can quite understand the interest your plant creates.]

— **STRELITZIA REGINÆ.**—I see this plant was exhibited at the Drill Hall on the 14th of February, and it is the first time I remember seeing it mentioned in the *Journal of Horticulture*. It is a long time since it was introduced into this country; yet how very seldom it is seen in gardens, which is strange with such a beautiful plant. There is much about it to recommend; of a bold and almost majestic type, easily grown, not much subject to insect pests, its curious but beautiful orange and purple flowers standing out amongst its fine evergreen foliage, at once arrest and receive a large share of admiration. Eleven years ago we had a plant sent us, or more strictly speaking, a very small piece of a plant—only three leaves, and almost rootless. It was potted in turfy loam and sand, and now it occupies a tub about 2 feet across. The plant is 4½ feet high, over 6 feet in diameter, and last autumn threw up twenty spikes of flowers. It seems to enjoy a light sunshiny position, as our plant has stood close to the glass at the south end of a span-roofed intermediate house, and the hot-water pipes pass underneath the platform on which it is standing about 1 foot from its roots. In the South I have no doubt this plant will do equally as well at the warm end of a greenhouse. Ours is a cold northern locality.—N. N. [The flowers sent were of excellent quality, and for distinctive beauty could not be surpassed.]

— **GARDENING APPOINTMENT.**—Mr. W. Abbey, late gardener to E. Chatrian, Esq., Woodbrooke House, Birmingham, has been appointed gardener to A. Balwin Bantock, Esq., Merridale House, Wolverhampton.

— **NICOTIANA AFFINIS.**—Seeds of the Sweet-scented Tobacco should be sown in a pan or box, and the seedlings pricked out to strengthen in other receptacles before potting or planting out. It is an excellent plant to produce sweetness, especially in the evening, at which time its flowers open, and the odour from them is exceptionally strong. In the day the blooms hang limp and loose, and appear not to like the light at all.—E. S.

— **DEATH OF MR. JAMES HALL.**—Mr. James Hall, who for the past thirty-eight years has been employed on the estates of the Earl of Scarborough, for the first seventeen years as gardener at Sandbeck Park, Yorkshire, and since as steward on the Lumley estate, Co. Durham, died on February 24th in his seventieth year. He is succeeded in the management of the Lumley estate by Mr. T. Garnett, who has been gardener at St. John's, Wakefield, for the past twenty-five years.

— **BIRMINGHAM GARDENERS' ASSOCIATION.**—The members of this Society assembled in force at the fortnightly meeting, on the 27th ult., to listen to a lecture on "Fruit Growing," by Mr. J. H. Goodacre, Elvaston Castle Gardens, Derby. The chair was taken by Professor W. Hillhouse, of Mason College. Mr. Goodacre, who is a well-known exhibitor of fruit and Chrysanthemums at the Birmingham shows, was accorded a hearty reception, and afterwards read a most exhaustive essay, which was highly appreciated, as it contained an immense amount of valuable information.

— **PROPAGATING MARGUERITES.**—White and yellow Marguerites may be readily propagated in a bottom heat of 65° to 70°. Select stout, healthy tops or side shoots about 3 inches long; remove the bottom leaves, and cut level close to a joint. Drain and fill 3-inch pots with a good mixture of sandy loam and leaf mould. Insert the cuttings round the edge. Four in each pot will suffice. Plunge the pots in cocoa-nut fibre refuse to the rim in a frame or box placed where the heat can produce the temperature named. When rooted, pot singly and grow without bottom heat.—S.

— **THE SILVER WATTLE.**—In the temperate house at Kew a plant of *Acacia dealbata*, 35 to 40 feet in height, is now very pretty, the head being smothered with flowers. For a large structure it is well adapted, as it can be taken up on a single stem until well above other plants, and then be allowed to branch freely, and so fill the top of the house without interfering with the dwarfier plants below. The fluffy globose heads—produced in large branching racemes—of bright golden flowers are well known to everyone as the "Mimosa," sold in such large quantities in florists' shops and about the streets. Besides being so pretty when in flower, it is worth growing as a foliage plant, the leaves being silvery and glaucous. It is a good natured plant, requiring little attention when planted out. It should be cut hard back every second year.—D. K.

— **THE TAXATION OF GARDENERS.**—There is a phase of this subject that seems so far not to have received the attention which it deserves, and that is the effects of such taxing or fiscal burthen on the provision of employment. We have but to glance just now through the advertising columns of gardening publications to note what an immense number of gardeners, young and old, are applying for places, showing how many must be in need of employment, and fail to find it. Is there any connection between the lack of labour in gardens, and the tax which a parental Government imposes upon a gardener's employment in private places? Of course, the assumption is that the employer pays, and as he is wealthy, how does labour suffer? But is the employer after all so wealthy? and in being called upon to pay a tax because he employs a gardener, is he not deterred, and seriously deterred, from keeping more than one or two perhaps, certainly as few as possible, because of the tax imposed upon gardeners in his constant employ? Stupid people, who cannot see an inch beyond their noses, reply, "Oh! if a gentleman cannot afford to pay the tax, why employ so many?" But those who look farther ahead realise that there can be no stronger reason urged for the abolition of the tax if it restricts labour, and that it does in gardens, and materially so, there can be no doubt. Practically this and some similar taxes are taxes or impositions on labour and employment, and it is because they are such every effort should be made to secure their removal. Were they so removed, who can doubt but that a great fillip would be given to employment in gardening, and that the entire community would benefit? Taxes we must have, but of all taxes, those which help to render employment difficult, whether in gardening or otherwise are the worst.—A. D.

SOUGHT AND FOUND.

WHO has felt what it is to lose an old and valued friend of forty-four years' standing—to wend his way for the last time around an old experimental garden, to linger alone through a gutted house, take a last long peep into every dismantled room, to hear the hollow boom of a closing door, and the grating sound of the key in the lock as it is turned to be taken away and handed over to the trustees? Twice I have survived the ordeal in regard to house and grounds, and I fear another flitting. However, the forces of life are irresistible; old associations must come to an end. But some of your readers may begin to think, What has that to do with water? Let me answer—everything for my theme, for without the above, that which is to follow would not have been written.

Those will sympathise with me who have experienced the difficulty in finding a house with a few acres of land attached prior to 1847, for the purpose of growing and experimenting with seedling Potatoes. I wanted a home in Berkshire near the town of Reading. I came to see the Cottage Farm, and recognised it would be a long uphill task to work it into shape; but where urgency drives, one cannot always choose. Altogether the place looked a sort of no-man's-land, with hedges broken down, and the forlorn little pond on which the house depended for its supply of water was filled by a recent storm with liquid the colour of coffee, which had run through a farinyard, and from thence by roadside rivulet for half a mile.

As soon as we had shaken ourselves into shape I investigated and found it would be essential to properly drain the land. John Tillen—"Drainer Tillen" he was locally called—seemed providentially to have been thrown in my way. He was nearly amphibious—never quite happy unless dabbling in the water meadows, had formerly assisted with the draining in Windsor Park, and in fact could do anything connected with water. He was upright as a ramrod. I inquired of him if he had been in the army. "Yes, he once served a month in the 'Royal Standbacks'" which I ultimately learnt meant the Berks Militia. I instructed him to form two tanks to catch the rain water from the roof. A few more days had passed, and then another confab. I said to "Drainer," "Look at that cow up to her knees in quagmire on the rising ground at the farther side of the meadow. I have roughly taken the level from thence at a tangent to this disreputable looking little pond, and without being a water diviner I feel almost certain there must be a spring there or thereabouts. Tell me, if you can foresee a difficulty in a drain being laid from where the cow is to this spot; it must be as near the surface as possible from here, and at the further end we can allow a depth of quite 6 feet." Tillen saw no difficulty, and after some labour and expense the operation was successfully carried out, and water fairly bubbled up at the depth of about 5 feet. We had tapped one of the springs of Berkshire—a boon indeed for this place, and I may say for my neighbours, for I say, "'Hoh!' come for water whenever you want it, but be sure and shut the gates after you."

It was all plain sailing afterwards, as I anticipated, and when completed the pure water entered a dip-tank holding over two hogs-heads. The "pond" was cleaned out. Bamboos and Kingcups were planted on its margin, goldfish are sporting in the water that seldom freezes, and has never failed us, summer or winter, since the spring was tapped.—R. FENN, *Cottage Farm, Sulhamstead.*

BOUVARDIAS.

ON looking over the plants which have been flowering during the autumn and winter, and which are at present in bloom, I can find none that have made a prettier picture than Bouvardias. Yet they are not grown in the majority of establishments nearly so largely as they ought to be, or as their merits entitle them to be, and many people who are often at a loss for small flowers in the midst of the Chrysanthemum season, quite overlook the fact that in the Bouvardia they have a plant that is of the greatest importance to them. Causes for this apparent neglect are not difficult to find, one being that cuttings have a happy knack of damping, but this may be remedied if proper precautions are taken, whilst another is the prevalence of insect pests, which if allowed to gain a hold will soon undo the work of a season.

Passing to the cultivation of the Bouvardia it may be stated that the plants can be raised from cuttings or division of the root, either of which will prove successful. The plants after flowering should for a time be kept on the dry side, and somewhat cooler, and then when introduced into heat will produce abundance of young shoots, these making the best of cuttings. When $2\frac{1}{2}$ or 3 inches in length take each shoot with a heel, and have ready some $3\frac{1}{2}$ or 4-inch pots half filled with fine crocks. Over these place a little rough leaf mould and fill nearly level with a light sandy compost. After the base of the cuttings have been carefully trimmed with a sharp knife insert them, and plunge in gentle bottom heat, being

cautious not to overwater, and just leaving a chink of air to dispose of superfluous moisture.

By this means there will be very few failures, and the plants will soon be ready for potting. A free open compost of leaf mould, a little loam and plenty of silver sand, will be found most suitable, placing the strongest plants in $3\frac{1}{2}$ -inch pots and others according to size. After potting place in gentle warmth, using water somewhat sparingly until the roots begin to work freely into the compost, when the syringe may be used to advantage with a view to keeping insects in check, as it is just at this time when the foundation is being laid that any inattention will soon cripple the plants.

When the pots are well filled with roots a compost may be prepared for the final potting, an excellent mixture consisting of three parts of turfy loam, one of good leaf mould, and sufficient silver sand

FIG. 39.—MR. R. FENN.

to keep all porous. I find 6-inch pots large enough for the first season, firm potting being quite essential if good, sturdy, short-jointed plants are to be secured. As the weather becomes warmer the plants may be removed to cooler quarters, a useful place being a cool frame, plunging the pots to their rims in ashes, which prevents rapid evaporation during the hot weather. As the pots become filled with roots weak liquid manure can be given twice a week with advantage, the lights of the frames being removed for a time, replacing during very wet weather.

In early autumn the plants must be removed to a house with gentle warmth, which may be gradually increased until a temperature of from 60° to 70° is reached. Abundance of bloom will be the result; in fact, every point will finish its truss of flower to perfection.

Division of the roots may be effected with a sharp knife, the after treatment being as advised for cuttings. If old plants are retained they furnish excellent material for cutting. The only care they require is to shake the roots out of the pots, reducing the soil, and repotting with a good compost into 8-inch pots. The following varieties are all excellent:—

Singles.—Boeki, deep coral, beautiful and free; elegans, large reddish scarlet; Humboldtii corymbiflora grandiflora, pure white, grand variety; Mrs. Robert Green, lovely salmon colour; Priory Beauty, perhaps the most charming of all, colour pale satin rose; President Cleveland, the finest of all scarlets; and White Bouquet, pure white sport from Vreelandi.

Doubles.—Alfred Neuner, white, excellent; flavescens, pale sulphur, vigorous; Hogarth, scarlet, fine; and President Garfield, pink, large truss, free.—R. PINNINGTON, *Roby, Liverpool.*

BEST POSITIONS FOR TOMATOES.

THERE are not any signs of decrease in the rage for Tomatoes; on the contrary, the evidence is all in favour of the presumption that this season they will be in greater demand than ever. Market growers utilise the whole of the body of their houses, planting transversely in well prepared borders. Some allow much more space than others, and after trying various distances, the conclusion arrived at is that an equal weight of superior fruit is obtained at a less outlay in labour and material by allowing ample space. I would advise owners in charge of small houses to crop differently, as they will secure heavier, earlier, and more saleable crops, if they utilise the roofs more and the body of the structures less.

Fresh soil is of the greatest assistance to the Tomato grower, and this is not often available in sufficient quantities to admit of a whole border being changed, but must be found when narrow beds along the fronts of houses only are provided for the plants to root in. In the case of houses with glazed fronts the ridges of soil may be formed on the floors, but the plants naturally make the best progress and produce the earliest crops when the soil is placed on slate-covered stagings over hot-water pipes, with, perhaps, a top-heat pipe just above the soil. A ridge 2 feet wide and 1 foot in depth of sound loamy soil is ample, but under and in front of this there may advantageously be 2 inches of ashes, made firm by having had pot plants on previously. Tomato roots revel in ashes, provided these are kept moist.

Most gardeners who have visited Mr. H. J. Jones of Lewisham during the summer will have observed that he can grow Tomatoes equally as well as Chrysanthemums. The bulk of the plants are trained up the roofs of small span-roofed houses, where they crop grandly. Mr. Jones is apt to draw attention to the small quantity of soil his plants are rooted in, but under pressure will admit that the ashes in front are crowded with roots, where they get the benefit of liquid manure from the soil, as well as occasional dressings of his own special mixture. It is only right to add that the varieties cultivated at Hither Green are among the heaviest croppers that can be named. The Cropper—an improved Ham Green Favourite—and the Champion, obtained by crossing the Cropper with selected Perfection—are both grand, and this I say after having had personal experience with them.

In many instances boxes or pots might well be substituted for a ridge of soil, and I prefer the first named when the position is much exposed to the sun or hot-water pipes, with no soil or ashes underneath for the roots to spread into. We frequently hear of the great weight of fruit produced by pot plants; but we cannot afford to be top-dressing, manuring, and watering all day long, and I invariably arrange my plants in pots, these running into thousands, where they can root out into either ashes or soil. No matter how well plants in 10-inch to 12-inch pots are attended to, there is always an improvement noticeable in their growth directly the roots reach the soil or ashes underneath. For roof culture the plants should be disposed 15 inches apart and confined to a single stem, nothing, as previously intimated, being gained, while much may be lost by crowding.

Shady positions do not suit Tomatoes, crops failing to set on plants that do not get a fair amount of light and sun. It is useless, therefore, to attempt their culture in well furnished vineries or Peach houses. For the first two, or three seasons at the most, after planting the Vines or trees it is possible to grow Tomatoes profitably in these positions, and if there is not any undue crowding of top growth, or neglect to keep the borders well moistened, no harm should result to the permanent crops from their association with Tomatoes. In these instances pot culture is desirable, standing the pots across the houses, midway between the rafters devoted to the growing Vines and in the spaces between and under the roof not occupied by Peach and Nectarine trees. I have also seen excellent crops taken from plants rooting in boxes disposed on the high back shelves of vineries and trained down the blank spaces between advancing Vines. Pots would not do in such positions, as they part with moisture too rapidly, whereas wood is non-conductive.

Amateurs who grow a few Tomatoes more or less successfully among their greenhouse plants will do well to remember that an ordinary herring box, costing one penny, will be much better for a single plant than a pot for which they have to pay fourpence. They ought also to avoid the varieties more noted for the size and handsome appearance of their fruit than for other good qualities. What they want in their small houses are sturdy growing, free setting, early ripening sorts, among which I would include Early Ruby and the comparatively new Comet. If they require a few handsome fruits for exhibition purposes a trial should be given Duke of York. I have noticed that many amateurs have small glazed sheds for potting and other purposes: the roofs of these should be covered with Tomato plants every summer, as they succeed fairly well in such positions.—W. LEGGOLDEN.

SPRING PLANTING.

DIFFERENCES of opinion undoubtedly exist regarding the respective advantages of autumn and spring planting for fruit trees. The advocates of each method advance their special reasons, and as these are generally founded on personal experience they are worthy of that attention and respect that should always be accorded to the observations of a practical man. Much can be urged in favour of autumn planting, and the most important of the arguments on that side relate to the expediency of the practice. Obviously, where there is a large

FIG. 40.—THE REV. H. HONYWOOD D'OMBRAIN.

extent of land to be planted, the earlier the work is commenced the better chance there is, in our uncertain climate, of having it completed in due time.

In reference to this, however, it may be said that where land has been properly prepared in advance the actual operation of planting need not be a very prolonged one, if an adequate amount of labour is available. Again, it is correctly said that planters who make their selections early in the season at the nurseries secure the best trees, and later purchasers have to be content with the leavings. There is something in this, perhaps, in certain cases, where the stock of particular varieties may be short, but as a matter of fact comparatively few growers do select their own trees, and the nurserymen very properly, in their own interests and those of subsequent customers, usually contrive to equalise their orders in a very fair way. There is another point in reference to this—namely, at whatever time planting is to be done, the selection can still be made in the autumn, and the trees will continue in as good condition for planting as if in the nursery quarters, provided they are carefully laid in trenches, the roots well covered with soil, in a position where rain cannot accumulate.

What may be termed the theoretical aspect of the question is briefly summed up as follows. It is contended that autumn planting allows a longer period for the trees to recover from the check and unavoidable injuries caused by removal. Further, that being in a state of rest they suffer less real damage at the time. There seems to be much reason in favour of these opinions, but are they supported by facts? Can any definite evidence be produced to prove that the results are precisely what they are expected to be? In my own experience I have had occasion to lift and examine trees planted at all times, and so far as appearance goes I have rarely been able to detect any improvement in the condition of the roots of autumn planted trees as compared with those removed at a much later period.

It is frequently said that the roots heal during a mild winter, and are ready to resume work in the spring. In some soils this is true, but in heavy cold land, and with the planting period followed by a wet winter, exactly the reverse occurs, and the damaged roots often decay. The time for healing wounded tissue is in the spring, when the vitality of the plant is re-awakening as it were, and it is then that damaged roots, stems, or branches, if cut clean with a knife, heal most rapidly and effectually. I am inclined to think that to obtain the advantages claimed for autumn planting in the respect mentioned, the removal should be done earlier than is the rule—viz., while the leaves are still on the trees, and when the weather and soil conditions have been right I have tried this with good results. Some judgment is needed, however, to avoid attempting it before the wood and buds are fully matured. I have proved beyond all question that the cuttings of Gooseberries and Currants inserted before the leaves have fallen, in a situation where they will not be dried, heal and form roots much more readily than if put in the ground at the orthodox time.

Having planted fruit trees at all periods, from the early autumn to the spring, partly as a matter of business, and partly from an experimental bias, I have satisfied myself that, under certain conditions, and with due care in the operation, planting can be as safely performed at the present time as in October or November, and sometimes with even better after results. The main point is to have the soil in good condition and to watch the trees closely in the event of an early start into growth being followed by a hot dry season, when a moisture-holding mulch over the roots, or the judicious supply of water, will prevent any serious results. It must be remarked in this connection that I always cut the trees back immediately after planting, and this reduces the danger of early growth being made before the trees can supply what is required from the roots. The lower buds are considerably longer in starting, thus giving the tree a better chance to recover.—L. CASTLE.

A REVERIE.

I SUPPOSE that no reader of the *Journal* will envy me the distinction of being one of the oldest contributors to these pages; such distinction as it is, Mr. Robert Fenn and I share it together. It is now near upon forty years since I became associated with it, and of what changes in men and things those years tell! My mind goes back to the old offices in Fleet Street, where Mr. Johnson and the Doctor used to sit enthroned. Then, what a long line of ghosts march past as one thinks on John Standish, Charles Turner, Donald Beaton (shrewdest and keenest of observers), and a host of others, whose facile pens used to fill its pages. And then, what changes of fashion in the things we had to do with. At one time one can remember how the Verbena, at another the Show Pelargonium, at another the Hollyhock, then the Fuchsia, the tuberous-rooted Begonia held their sway in our gardens, until they had reached such a degree of perfection that growers were contented with the package of seed, instead of the collection of named varieties.

Those years have seen also the introduction of new claimants, for what was the Japanese Chrysanthemum and the Gladiolus forty years ago? Those years have witnessed, too, the rise and fall of the bedding-out system of gardening, which at one time absorbed all the space, time, and energy of those who had charge of private gardens; and when they met, the talk used to be of how many thousands of "Geraniums," Verbenas, and Calceolarias they had put out for bedding. But here again time has wrought its changes, and the herbaceous border, with its more interesting occupants, now commands the attention of the gardener.

What developments of the future we may look forward to we cannot tell, but I hope and believe that when the pens drop from our hands, others more vigorous will take them up; and at any rate, it may be permitted for me to wish a long course of prosperity to the *Journal*, which I have humbly, but I trust faithfully, striven to uphold.—H. HONYWOOD D'OMBRAIN.

"FOR GARDENING AND GARDENERS."

THE use of mottoes is ancient, and, strictly speaking, should bear allusion to the achievement. This characterises that of the *Journal of Horticulture*, for "gardening" means work done in a garden, and "gardeners" imply the workers. A garden may be defined as a piece of land of any description or size, attached to or connected with a residence, and set apart, either for the cultivation of plants and flowers, or for the purpose of growing fruits and vegetables. The love of a garden and its products, in every way, betokens inborn notice and appreciation of the beauties and utilities of Nature. Flowers, and the plants specially grown to produce them, have a universal charm, presenting a means of endless study and enjoyment. Fruits and vegetables are of the greatest national importance, as representing a necessary source for supplying wholesome food.

The value of a garden cannot, therefore, be over-estimated, as it tends to promote health—the first wealth—and is also, by the very nature of its products, not merely conducive to the well-being, but essential to the existence of society. A garden, consequently, of some description, wherever practicable, in conjunction with every dwelling house, is one of the prevailing characteristics of civilised life, from the highest to the lowest class. The form and extent of the garden necessarily vary according to the amount of available space to be enclosed or the requirements and taste of those who have to incur the expense of preparing or maintaining it.

But of all departments of gardening the fruit and kitchen garden is most important on the score of utility, and requiring, whether small or large, the exercise of considerable skill, judgment, and forethought to attain to satisfaction in crops. The higher branches—such as the forcing of flowers, fruits, and vegetables, cultivation of Orchids and other plants under glass—are included in the term gardening—the art which enables mankind to make the most of Nature's gifts.

Gardening means not only to increase but to improve the produce of the land. Therefore every gardener—boy and girl, youth and maiden, man and woman—whosoever attains to this in greatest measure, not only derives most interest, pleasure, and profit, but does a real service to the country. All gardeners, amateur and professional, learn from Nature, from patiently tried experiments, from failure as well as from success, what is the best means of accomplishing

FIG. 41.—MR. GEO. ABBEY.

an object. No small advantage to them is that nearly all that can be known, and quite all that need be known, can be learned from carefully reading the information transmitted from the older to the younger branches of the craft, and handed onwards with the gradual but certain improvements of the age.

In this work the *Cottage Gardener and Journal of Horticulture* has borne a full share for half a century, and still exists, "as a giant refreshed," to maintain right to its motto, and achieve in the future, as in the past, everything desirable "for gardening and gardeners"—G. ABBEY.

COGITATIVE NOTES.

THE month of March is a busy time with the cultivator of Chrysanthemums, no matter whether it be in the production of exhibition blooms or a supply of flowers from the open border for the enthusiastic amateur. It is surprising what really good blooms many amateur cultivators produce. Enthusiasm coupled with a keen desire to pick up any useful hint is what goes a long way to achieve desired results. Any hint, then, that we can give for their benefit is time well spent. I do not mean, though, that the few remarks I shall make are intended only for amateurs. They are applicable to all interested in Chrysanthemums, whether as cultivators or on-lookers.

Cultivators make it a rule to insert many more cuttings than are required for final growth, and a wise plan too, especially now that so many collections are affected by the new disease—rust. I assume I am right in placing the word "new" to this disease which is agitating so many growers at the present time. The Chrysanthemum has been one of our most popular flowers for fifty years. It does seem strange that it is only during the past season that this enemy has taken so deep a hold of the mind of many persons. Neglect during the infantile stage of the disease brings disaster. If cultivators would keep a bottle of methylated spirit and a small camel-hair brush handy, and touch the rust spot with the spirit the moment it is visible, we should not hear nearly so much about the trouble.

Now is the time to decide on the selection of varieties and the number of plants of each to be grown. None but the best must be included. When I say the "best" I include those varieties that are difficult of production, as such weigh heavily with the judges in close competition. The inexperienced are liable to give way to personal sentiment in the selection of varieties. To illustrate my meaning, compare two varieties like Mrs. C. Harman Payne and the new Mrs. Barkley, both somewhat similar in colour, yet so distinct in point of quality. Again, take Madame Carnot and Souvenir de Petite Annie. The latter I have frequently heard praised by amateurs, and certainly it is a deserving variety for decorative use owing to its freedom in flowering and dwarf habit. Individually, too, the blooms are perfect, but not large enough for present day requirements in the exhibition arena. Madame Carnot I still regard as an ideal type of a Japanese Chrysanthemum.

Some cultivators I find adhere closely to such yellow varieties as W. H. Lincoln, simply because it is dwarf and easy to grow. The newer R. Hooper Pearson, for example, is infinitely superior for the show board. Where the former would perhaps gain three points the latter would probably secure five points. Such comparisons might be continued indefinitely, but sufficient has been said to afford the inexperienced ample food for cogitation on one of the most important details in connection with exhibiting. No two varieties that bear a close resemblance should be tolerated. All possible precaution ought to be taken to prevent disqualification. Another point in selection, and one that is worthy of the utmost consideration, is that of overcrowding the plants. Far better grow one hundred well than spoil double that number.

In many instances the bulk of the early-rooted plants are now ready for their first transfer to larger pots. It is a mistake to allow the roots to twine around the inside of the cutting pots. A stout foundation is essential to success. I know cultivators who have in the past striven hard to prevent a robust growth of stem, but who have never reached a high position in the prize list, and who are now seeking to grow the plants as strong as they can. I do not think it is possible to grow the plants too stout at the base, provided, of course, the growth afterwards is regularly and gradually matured, and not hardened by withholding water when it is perceived that the growth is gross and sappy.

A compost of two parts of fibrous loam to one of leaf mould and half-decayed horse manure, with a plentiful addition of sand if the loam be at all retentive in character, should be the means of laying a good basis for early growth. Should there be any doubt about the loam not being of a sufficiently rich character, add to every bushel of the compost 1 lb. of Thomson's Vine manure.

Much has been written in catalogues, and elsewhere, of the desirability of topping the plants in the incurved section. My opinion is if there were less interference with the natural growth we should see better examples than is now the case. No one who visits the exhibitions of to-day can fail to see the decrease in the quality of the exhibits as compared with five years since, or even less. What with the adoption of wrong methods of culture and the inclusion of varieties not belonging to the section, the Chinese incurved Chrysanthemum has fallen below its reputed standard of quality, and, I may say, of popularity also.

The preparation of the soil for future use must have attention. In many instances the necessity for the employment of chemical manures as a means of enriching the soil is absolute owing to various circumstances. For the final potting of the plants in May and June, no matter for what purpose they are grown, the present is not too early to prepare the compost. It is useless to mix this on the day required and then expect to get full benefit from the manures employed. For example, phosphatic manures (like bone, horn, and hoofs) require long periods for assimilation of their virtues by the soil before the plants can derive benefit. Basic slag is now largely utilised by cultivators, and this certainly should be mixed with the soil at the rate of 2 lbs. to one bushel of compost at least a couple of months prior to potting. Presuming, then, that freshly cut turf is to be employed the present is a good time to stack it in layers, sprinkling the basic slag between. Freshly gathered horse or cow manure may be substituted for the latter if the turf is from a sandy soil. When potting time comes the whole would be thoroughly incorporated.—E. MOLYNEUX.

HARDY FLOWERS.

GARDENING is an eclectic art, and has within its domain scope for workers of many tastes and many methods. Like all other arts it has its waves of fashion, when one class of flowers or one style of gardening is followed by the many who are less influenced by true love for gardens and flowers, while comparatively few cling to their old favourites. Now that the tide of popular favour is strongly in support of hardy flowers we may say that they are happy who, through good report and ill, cherished their herbaceous borders with the plants they contained. They have their reward now when these flowers are more appreciated than ever before. The old borders are coveted now with their treasures of old-established plants, which look so well compared with the small plants found in newer gardens.

One can hardly overrate the merits of the hardy flowers. They can be had in bloom, without the expense of glass houses and hot-water pipes, nearly all the year, save when bitterest frost or thick snow prevails. With the coming of the new year we may have the Snowdrop, the Crocus, the Christmas Rose, the Winter Aconite, the dwarf Iris, the golden Jasmine on the wall. The earliest are followed by the later Snowdrops and Crocuses, the Snowflakes, the early Saxifrages, and many more, among which appear the earliest Daffodils. These Narcissi, with those which follow, provide in themselves a long and precious procession of beauty which passes slowly—yet too quickly—before our delighted eyes, until May dissolves into June and summer has come with its luxuriant, lavish display. We cannot stay to tell of the gems which accompany the Daffodils. We think of the clustered bells of the Squills in their many forms, blue and white and pink, but we cannot read in their flowers the sad refrain of "Ai Ai" with which legend has marked them. Our thoughts of their loveliness are too happy for that. We think of the frail Windflower, with its sister, with scarlet or with purple cup, which we call the Crown Anemone. We think of sheets of snowy Arabis; of purple Aubrietia; of golden Madwort, with many others whose names are imprinted deep in the hearts of those who love the flowers of spring. The Daffodil has a retinue worthy of her beauty.

As these fade the wealth of summer is with us. The Tulip cups are its heralds blowing loudly the trumpet call, the fanfare which tells of the approach of the Lily and the Rose; the Iris, the Larkspur, the Pyrethrum, the Sunflower, the Enothera, the feathered Spiræa, the Pansy, the Viola, the Marigold, the Aster, the Stock. One may well pause, nay, had better cease, in the attempt to tell of the hardy flowers of summer time. If not innumerable there are too many to name, without even venturing to faintly limn their beauty and their ways.

With golden autumn and the dying days of the year the hardy flowers come with richer and then with a sadder loveliness. There are golden Sunflowers, great Dahlias, exquisite Gladioli, flaming Kniphofias, with many other perennial flowers and the lovely annuals, some of which, because of their self-sowing habit, may as truly be called perennials as those which yearly from the mother root send up their leaves and flowers. Then come the Starworts, with their sober,

beautifully coloured flowers, the Meadow Saffrons, the autumnal Crocuses and Snowdrops, which complete the cycle of the year.

As we think of them we think, too, of their colours and hues; purest white passing from creamy white through light yellow to deep yellow and orange; palest flesh passing through pink to scarlets and crimsons of deepest dye; faintest tinge of blue ranging through the gamut of shades of colour to deep blue and black purple. We cannot tell of the shades, the tints, the markings which complete the glory of the flower. Leaves also give us their share of fascinating grace and interest. Greens and greys, silvers and glaucous blues, bright or deep red brown, are there with forms innumerable. Entire, arrow-shaped, lobed, pinnate, lance-shaped; smooth and rough, hairless or spiny, many are the peculiarities and beauties they show.

Nor are we less pleased with the habit of the plants or the form of their flowers. Towering aloft and stately some are, while there are all sizes until we reach the creeping plant, which scarcely rises above the soil. Bells and cups, quaint hoods, tube-like blooms, cup within cup, bell within bell, hood within hood, creamy plumes, sprays of foam-like bloom.

If we add to the thought of the charms of the hardy flowers that of the little care they ask at our hands; their perennial reappearance; their fitness for entwining themselves into our fondest memories; their innate beauties of form and colour are enhanced to our minds, and we prize them more and more as time rolls on.—S. ARNOTT.

FAULTS, FALLACIES, FAILURES.

Why is it that in the Midlands one so frequently hears the advice, Do not procure fruit trees from the South? This is a question to which I have never had a satisfactory answer, and I always press home the adviser for his reason. The invariable reply is that southern trees are "soft" and do not answer when sent north, and that trees from the north are so hardy that when sent south they are bound to thrive.

Now, there is nothing like the logic of facts to "floor a fallacy," and my bit of logic is the condition of the trees in the Derbyshire County Council fruit plots. The whole of the trees and bushes were procured from southern nurseries. Many of those planted in 1893 at Duffield are now pyramids, upwards of 12 feet in height; grand examples are they of healthy growth, symmetrical development, early and persistent cropping, exemplifying the beneficent influence of the broad-leaved Paradise Stock in affording robust growth in conjunction with the early development of plenty of blossom buds. Equally remarkable are the standards, all of them being in a satisfactory condition of development, some having heads 12 to 14 feet in diameter. Quite as satisfactory are the trees planted in 1895 in the fruit plot at Matlock Bridge. Fortunately, they are before the public, and tend, better than anything I can say, to refute the fallacy.

It is precisely this taking care of the trees that I had in my mind when I sat down to write this note. Can anything be more tantalising, or more unsatisfactory, than the condition of many a collection of young fruit trees during the first year or two after they have been procured from a nursery and planted in their permanent quarters? Many a time and oft have I been called in to advise the disconsolate owners of such trees. There stand the trees, alive, it is true, but only putting forth leaves; there is nothing like free growth upon any of them, and, yet, how well they looked at the nursery! There the growth was positively rampant. Why should mere transplantation induce so great a change? This is precisely the point. Let us look into it a bit. It is the nurseryman's business, as it tends to his profit, to have his young tree stock in perfect health and vigour—vigour, especially, he must have. He knows full well that to this end his soil must be abnormally rich in fertility; he makes it so, and keeps it, either by liberal dressings of natural or chemical manures, or both. In this matter his ideas of liberality are far and away beyond those of the ordinary practitioner. Gardeners are not bad hands at cramming the land with manure, but where the gardener uses 50 tons to the acre the nurseryman will use 100. The gardener, perforce of circumstances, often falls short of his fifty, but the nurseryman is bound to keep the land up to his standard, or his stock would deteriorate. Surely, the sight of the magnificent growth of nursery stock should make one thoughtful and cautious—but thoughtful, especially. An intelligent man would not only endeavour to grasp the reason why the trees had such clean, healthy, vigorous growth in the nursery, but also to see how he could induce the trees to grow with sufficient vigour for his purpose after he has them in his hands.

To take a very common case—that of the planter of little experience. Partial or total failure is often the result of his attempt to establish such trees in his garden. He has been advised that he should not use manure in preparing the soil for the trees. Acting on the advice which it may be he has seen over the name of a well-known fruit grower, he plants the trees with all due care, but

without manure, in soil which, if not absolutely poverty stricken, is low in fertility. Can it be matter for surprise that feeble growth is the result, or that the gardener is disheartened, his employer disgusted? Not a pleasant thing is it to be asked to advise in such a case. How much rather in the interest of both master and man—aye! and of the nurseryman too, would one prefer to be consulted beforehand!

It may be as well to remind beginners that abnormal fruit bud development is not always owing to poverty of soil. It is frequently a result of transplanting both in Pears on the Quince stock, and Apples on the Paradise. In the autumn of 1894 I had a young pyramid of Cox's Orange Pippin practically without a wood bud, but with a

FIG. 42.—MR. E. LUCKHURST.

profusion of blossom buds. The tree was then cut hard back behind the blossom buds; nothing was done to the roots, as I knew the soil was rich enough. The result was vigorous growth, and the tree is now a fine specimen.—EDWARD LUCKHURST.

—COVERING OUTSIDE VINE BORDERS.—There is a variable practice appertaining to Vine borders in the matter of winter protection, some believing in a heavy coat of manure, others of leaves, and some nothing at all. So long as mild weather occurs the latter course may not bring about any serious consequence; but deeply penetrating frosts undoubtedly are not beneficial to the fleshy and fibrous Vine roots situated near the surface. The residue, too, from decaying manure has a tendency to encourage and foster the increase of surface roots, which is so pleasing to the grower. I have noticed that unprotected borders present few surface roots, no matter how otherwise treated. A heavy coat of farm manure is not desirable, though of the two evils the latter is the less one. To my mind freshly gathered tree leaves form an ideal winter covering placed fairly thickly over the border surfaces, and these covered with sufficient strawy material to prevent their being disturbed or carried away by the wind. These become wet during the winter, and in this state are cold in spring, and houses started fairly early are benefited by having the covering removed during the prevalence of sunshine, and replaced again at night. During a winter's use decay will provide a fair amount of broken leaf, which, with the presence of surface roots, will tend very much to their increase; and if, when these are finally removed, a layer of horse or cow manure is spread on the border these roots will benefit the Vines materially.—R. A.

CHERRIES FOR GARDENS.

THESE delicious fruits are so much appreciated both for dessert and for preserving, that it is a matter of surprise that greater efforts are not made to grow them more largely in many gardens. They will not, of course, succeed everywhere, but undoubtedly there are numerous gardens in which they might be successfully grown in considerable quantities. This matter has forced itself upon my mind at various times when living in different parts of the country, as in every county in which I have sojourned I have always met with a few trees which were thriving satisfactorily, and I fully believe that if a suitable site is selected where the soil is a fairly deep loam resting on a sandstone or calcareous strata, Cherries may be well grown in all counties south of the Trent. In the noted orchards of Kent the soil is a good brown loam, resting on the Kentish rag, which insures ample drainage; and one of the most important points to observe in Cherry growing is to see that the drainage is thorough. In low-lying water-logged land they will not thrive, neither will they on land which has a clay subsoil, even though the position is undulating. For preference a site with a gentle slope to the south should be selected, but in some parts of Kent Cherries succeed splendidly on sites which slope sharply to the north.

Having now indicated the character of the soil and the situation to be preferred, *Journal* readers will, I think, agree with me that these favourable conditions may be met with in numerous gardens throughout the country, and I trust that many gardeners who have not yet made an attempt at Cherry growing will begin at once while there is yet time to plant this season.

An open situation should be selected, and if it is intended to plant small fruits between, standards worked on the Morello stock should be obtained, as those worked on the wild Cherry resent disturbances at the root. This fact probably accounts for the Kentish practice of growing Cherries almost exclusively in orchards. If the trees are planted 30 feet apart, ample of room is allowed for them to develop into fine specimens capable of bearing many bushels of fruit. In the majority of gardens, however, a large breadth cannot be devoted to Cherries. What is required are a few trees of several varieties which will give a succession of fruit. In such cases bushes meet the requirements in every way, and I prefer them to pyramids, because they may be kept in proper form without much pruning, and, moreover, prove extremely prolific. If bushes are planted on either side of a walk, 12 feet apart is a suitable distance, if in a separate quarter 15 feet.

If the whole of the ground is trenched, so much the better; but when this cannot be done, holes 5 feet in diameter ought to be taken out to a depth of 2 feet, the subsoil broken up, and the hole partially filled with some of the best soil at hand. As a matter of course the points and broken portions of roots should be removed, those remaining being spread out in layers and covered with soil, the uppermost layer being about 2 inches below the ground line. After the planting is completed, a mulching of rough manure or leaves will do much toward securing a good start by helping to keep the roots uniformly moist. Bush trees should be worked on the Mahaleb stock.

After planting, cut the shoots back to within 9 inches of their base and shorten the leaders again the following year, till the requisite number of branches is obtained; these leaders may then be allowed to extend from 9 inches to a foot each year till the desired height is obtained, and from that time be annually pruned to within one or two eyes of their base. Early in June the side shoots should be pinched to three leaves, and the leaders to ten or twelve. When this system is followed, very little autumn pruning is necessary; it only amounts to shortening back a few spurs here and there, or removing others as they become old and gnarled. This spur system of pinching and pruning is well adapted for such varieties as Early Rivers, Early Red Bigarreau, Frogmore Early, May Duke, Governor Wood, Late Duke, Waterloo, Black Eagle, and Coe's Late Carnation.

The several fine Bigarreau and Heart varieties do not succeed well when grown in the bush form if closely stopped and pruned, but they bear freely on young shoots of the previous year's growth in a similar way to Morellos. The best way to deal with varieties of this type is after the requisite number of branches (nine) are obtained to allow them to grow at will, simply thinning out the shoots freely each year after the crop has been gathered.

I have often been surprised to find Morellos are not more generally grown as bushes, for enormous crops may be obtained from them when grown in that form. The fruit is not quite so large as that produced by trees against walls, but if all items of culture were taken into account over a series of years, the bush form would, I think, be found the more profitable method of growing this popular sort.

I do not intend in this note to deal in detail with Cherry culture on walls, because nearly all gardens contain a few trees grown in that way, but I should like to draw special attention to a fine early variety,

which is not so much grown on walls as it should be; I refer to Black Tartarian. If fan-shaped trees are planted and kept in check by summer pinching superb fruits may be obtained, of which any exhibitor might well be glad setting up a collection of fruit at some great show. —H. DUNKIN.

THE WEATHER.

THE Americans say we have no weather in England, only samples of it; at any rate, it affords an endless matter of interest. We once belonged to the Continent, but I apprehend have got on

FIG. 43.—THE REV. ALAN CHEALES.

considerably better since the connecting link gave way, and the shallow 200 feet deep channel was hollowed out. It is something to escape such visitations as that New York has just had; even if an April day here can, and sometimes does, include samples of the four seasons in its twenty-four hours. The Gulf Stream, moreover, is something to be thankful for, though it occasionally sends us a long series of damp depressions. The Banks of Newfoundland are said to be the breeding place of half our weather. The Gulf Stream there meets the Arctic Stream, and something like endless fogs on the Banks is the consequence. "Fog, dog, and cod" are said to sum up Newfoundland. But uncertainty is the only certain thing about English weather. As some rude person has said,

"Coy as a woman, and fickle as she,
No one can tell what the weather will be."

At least, till it is past; and then we may moralise. Last year broke all records; its drought, its north winds, its hot September had all much unprecedented, especially here, the seven days above 80° during the month. For the last three years this portion of the Thames Valley has been like King Arthur's

"Island valley of Avilion,
Where falls no hail or sleet, nor any snow."

And the rainfall, though doing its best, has not yet recuperated. Our 1898 record was some 4° under the average, whilst the long lack of snow must have told heavily on the springs, which may be some time in recovering. At this point, however, I feel called to recognise Mr. Mawley's never failing annual reminder. Is it also a permission? "*De mortuis nil nisi bonum*:" "Do not abuse the year till it is passed."—ALAN CHEALES, *Reading*.

GARDEN INSECTS AS WEATHER PROPHETS.

Just at this important season, when winter is losing its grip of the land, and signs of spring are appearing, a sight rather familiar to us is that of a host of midges, or small gnats, disporting over some garden walk. I have also noticed them by thousands along a road, having evidently descended from sloping fields above, attracted by the sunshine. Of course there cannot be a fresh batch of these flies every time we see them, so that at intervals they must hide amongst grass or in shrubs. They do not seem to be vocal, like others of the tribe, so how the signal to assemble is given we cannot tell. Curious to note, the flies will execute now and then a double movement, rotating in the air regularly, while they are also moving as a body towards some direction. People sometimes hesitate to pass through a swarm of them, lest they should be stung, but I believe the insects are harmless, though stinging gnats may occur in parties near streams. What is specially interesting about them is that their dances are thought to betoken an improvement of the weather. I suspect their indications are deceptive, for I have known a wet morning to follow a turn-out of midges at dusk; this may be true, that when they appear on a rainy day, the sky will clear shortly.

Newspapers occasionally narrate the appearance of butterflies on the wing in January and February, the conclusion being drawn that they are signs of an early spring; but that does not follow. Brimstone and tortoiseshell butterflies hibernate in nooks and corners; a fine winter's day sometimes rouses them, and out they come, probably to fall victims to a hungry bird; they may also be dislodged by the clearing of a barn or the cutting up of a woodstack. Nor can the emergence of such moths as come forth at the beginning of the year, should it occur about the usual date, surprise the naturalist; it is their season, if to the ordinary person they appear unexpected objects. Those of the Hybernias that emerge between November and March do not vary much with the weather, yet in a sense such moths may be called prophets—one, indeed, common everywhere, bears the name of the Spring Usher. These are slim-bodied insects, with wingless females, some of which are too well known as parents of broods of caterpillars which strip the foliage.

Every gardener wishes to have a calm and genial spring, and many caterpillars might join him in the desire, and it is one consolation while keen east winds blow, that they are destroying hosts of his juvenile enemies who have quitted the eggshell rather soon. Spring rouses the hibernating caterpillars by degrees, some venture out early, others refuse to move if the warm days are few. Should a gardener see by the wayside on Chickweed or Nettle the shaggy caterpillar of the tiger, it is a hopeful sign, indicating that the season is making progress towards warmer nights. Again, should he detect upon Gooseberry or Currant the spotted caterpillar of the currant or magpie moth stretching itself after its long nap, he may conclude the insect is aware that the buds are just expanding, and it is a warning to look after those of the brotherhood.

Good old Moses Harris tells his readers that, from his experience, the flight of the small white butterfly early in the morning seldom fails to foretell a fine day. Spiders, too, are natural barometers; if heavy rains have damaged their webs during the night they bestir themselves the next morning should the sky be likely to clear, but when more rain is approaching they coil up under a leaf and wait for better days. On those dull days of May when an east wind blows yet the air is rather still, the migration of aphids in the winged form occurs. In some way unknown to us these tiny insects perceive the approach of the time when they may safely fly, and by watching we may see them preparing for the weather that country folks call a "blight."—J. R. S. CLIFFORD.

WHAT IS IT?

YES, what is it? There is something in the air—the sky is full of portents—great events are at hand, and we all are standing and watching with breathless expectancy.

What do we want? what do we desire? Life—new life in our veins—life which makes the old young again—life which makes the young intoxicated with joyous hope and passion. The new life breaks slowly at first, we are not quite sure if the awakening has begun in earnest; there is a stir, a gentle rustle among the dry leaves, and then all subsides into winter stillness again. But the movements are oftener repeated, the rustlings are not so subdued, and a harbinger of life appears here, there—just forerunners of the great revival.

The purling stream, with its gentle murmur, wakes the first note, to be quickly taken up by the starling and the blackbird, two such busy individuals, careering over the lawn intent on worms, big or little. Indeed, no worm seems too big, and a tussle between the bird and its most unwilling victim, is one of the pleasant sights I witness from my window.

The voice of the dry searching wind forms an orchestra of its own;

E. by N.E. it comes tingling and smarting, fairly beating us into action. "No time for loitering now," the wind says: "I have dried the damp soil and made the highways smooth and clean. Oh, son of man, I have done my part, now do yours. Give old Mother Earth her wonted tribute of seed, and plant and leave her to nourish and bring up children." The days of winter idleness are over, the days of healthful outdoor work begin, and he is but a laggard who folds his hands and will not face the sharp sting of the morning air.

The flower beds appear eruptive; the upper crust of the earth is broken, and a night's rain and a day's sun serve to discover little bayonet points of green. We shall have a quick succession now. Fresh and tender green, the harbingers of our precious floral gems.

Our winter flower, the saucy Aconite, is over; the Fair Maid of February treads quickly on his heels, only to be followed by the clusters of Crocus, gold and imperial purple, which in their turn yield the sceptre to the myriad hosts of Daffodil and Narcissi, and who dispute with Hyacinth and Tulip place and homage. We are wondering what damage King Winter may have done to our Queen; it is too early yet to arrive at a just estimate, but all signs are hopeful. The late and warm autumn proved a grand ripener of wood, and the bark looks healthy and vigorous. Do not be led, my friend, into the error of too early pruning, the frost King may yet have surprises for us, and ours is but a treacherous clime.

The early Violets have been for some time in bloom under the shelter of the old wall; we shall soon be searching bank and dell. Do you know where the first Primrose is found? Ah, yes, the secret is mine. You shall have a share of my spoil, but you shall not know my happy hunting-ground. Nature reveals her secrets to her lovers; she is no coy shy beauty, but she wants no half-hearted admirers—all the heart or none, she cries.

It were folly to say the trees and hedgerows are as dead; see how

FIG. 44.—MR. J. R. S. CLIFFORD.

all the leaf buds swell and shine, and in the Pine woods is incense worthy the dwelling of the Most High. The natural world is brimful of delights; there is no corner too mean, no plant too humble to be left out in this great regeneration. There is the Fern-like Corydalis at the window, the springing roots all around every inch of the dear garden bearing its own peculiar treasure, the accumulation of over twenty years, each with its own history, each with its memory of glad days or sorrowful days, and they all are passing into the hands of strangers. The last good-bye is said, and the happy country life is exchanged (oh, sorry exchange) for a life of mere existence in the murky town.—THE MISSUS.

BLENHEIM.

To all horticulturists the name of Blenheim will be familiar as referring to one of the most celebrated estates in the country; while to students of history it recalls the glorious victory that was gained by British arms under the first Duke of Marlborough at the battle of Blenheim. The demesne is so crowded with historical interest that a few notes must be given on this aspect, relative to which we cannot do better than let Mr. John E. Jefferies of Oxford speak, for no one in the horticultural world is better qualified for the task.

“It may be said of Blenheim that its stately grandeur is of universal fame. The historical associations that are remembered therewith, as well as its impressive appearance from various points of view, invest it with an interest and charm that in a measure correspond with its fame; indeed, it is a place of permanent interest to visitors from far and wide. The park, 2700 acres in extent, with a circuit of about twelve miles, and the palace covering three acres of ground, represent a nation's reward to John, Duke of Marlborough, in the reign of Queen Anne, for victories gained during the wars of the earlier part of the eighteenth century. The Parliament of the day voted a grant of half

On entering the park from this point, a view of the palace is obtained with a part of the lake, 250 acres in extent, that until recently contained a vast accumulation of aquatic weeds, which seemed as though they would become a permanent disfigurement. To eradicate them was a work of great magnitude. However, it was laudably undertaken by the present Duke of Marlborough, who should be congratulated on the great improvement that has been effected in satisfactorily accomplishing a work that so manifestly enhances the grandeur of this historic domain. Now the lake is a charming feature in a most pleasing landscape as viewed from the broad carriage drive at an elevation of more than 100 feet above its surface, with the distant massive stone bridge and the extensive woods that reach far beyond, completing the beauty of the picturesque scenery. The water is supplied by the river Glyme, which, after flowing through the estate, joins the Evenlode, and is finally discharged into the Thames a few miles distant. The genius of “Capability” Brown transformed what was here a mere rivulet into an extensive lake, and its formation may be regarded as one of the chief accomplishments with which his name is associated. The cascade at the lower end of the lake forms an appropriate addition, and is a good example of this description of construction, and does much to heighten the effect of the surroundings.”

FIG. 45.—BLENHEIM PALACE, NORTH FRONT.

a million of money for this purpose, and the erection of the palace was commenced in 1705 from designs prepared by Sir John Vanbrugh, but the Duke died in 1722 without having resided in the mansion.

“The domain is distant from Oxford eight miles and is contiguous to the town of Woodstock, a favourite forest retreat of the Saxon kings in the ninth century, where, in 866, it is recorded, Ethelred, brother of Alfred the Great, built a palace in the park that became the birthplace and residence of future monarchs. It was here that, it is said, King Alfred translated a classic of Boethius, ‘De Consolatione Philosophiæ,’ an edition of which, edited from the MSS, is just issued from the Clarendon Press, Oxford. The ancient palace, although sought to be preserved by Vanbrugh, was demolished by command of the Duchess in 1709. It was situated a short distance from Rosamond's Well, which is still a never failing spring, and is to be seen surrounded with masonry surmounted with an iron railing. Rosamond's residence was outside the park wall, and is supposed to have been approached by a tunnel; it was ordered to be restored by Edward III., who, for a few years after his marriage, resided principally at Woodstock.

“Blenheim Palace is approached from various directions, the two principal entrances being from the town. That used by the public is through the triumphal arch, which is of the Corinthian order of architecture, erected by order of Sarah Duchess of Marlborough, in 1723.

Such is an outline of historical Blenheim. Pages might have been written with the greatest ease, but Mr. Jefferies, having sifted the grain, gives no chaff, and so we may now, except for one point, leave it and turn to other features. In his concluding paragraph our contributor adverts to the Glyme as a rivulet converted into a lake. There has always been some question as to whether there was not always a lake between the mound on which stood the ancient Manor of Woodstock and the rising ground that is surmounted by the palace. After closely examining an old print of the park as it was said to be in about 1700, one is convinced that Mr. Jefferies is correct in his assumption, as the course of the Glyme can be readily traced as it winds through the meadow. The palace itself stands magnificently, and considering the area of ground covered, it is needless to say that it is imposing, though perhaps somewhat too dwarf and flat to be really grand.

Pass we now to the care of Mr. Thos. Whillans, who has been located for a dozen years, and whose charge, which reaches a total of about 133 acres, includes pleasure grounds, flower and vegetable gardens, with numerous glass structures. From the palace to the gardens one must traverse hill and vale for about a mile, but that distance is likely to be indefinitely extended to the visitor whose tastes are either horticultural or aboriginal. From the latter aspect both the greater and the lesser parks are peculiarly rich, though not so much in variety as in the excellence of the species that thrive. Oaks, for example, are seen in

FIG. 46.—ITALIAN GARDEN, BLENHEIM.

vast numbers, and in almost all stages, but the veterans that have suffered from the hands of time take the lion's share of admiration. Elms, too, are splendid, as are various Conifers with Cedars, in exceptional form. It is useless pretending to give lists of names in notes of this nature, as if such were done the whole available space would be occupied by them alone, to the exclusion of items that are certainly, from every point of view, more interesting. Destined to still further enhance the interest of the estate are the *Abies glauca*, planted respectively by the Prince and Princess of Wales, Princess Victoria of Wales, and Princess Charles of Denmark on the occasion of a visit in November of 1896.

Perhaps the most advantageous place at which to commence will be the palace, whence may be obtained views that are charmingly diversified and yet simple. The principal entrance faces the north, and from beneath the noble Corinthian columns that support the massive masonry can be seen the monument towering to a height of upwards of 134 feet, that was erected to the memory of the conqueror of Ramillies, Oudenarde, and Malplaquet. This, similar to the mansion, stands on an eminence. In the valley between is a portion of the lake spanned by the grand bridge that is about 135 yards in length, and of proportionate width. From the south front, where are situated some of the state apartments looking over an expanse of lawn that has an area of 25 acres, and to pastoral scenery beyond, the eye finds the tower of Bladon Church in the distance. On the east lies the Italian garden, and on the west the ground falls to the lake with Rosamond's Bower to the right, and the pleasure grounds on both sides of the water, as well as the cascade on the left.

The Italian Garden, to which cursory reference has just been made, is very extensive, and must, when occupied with plants in the summer, present a gorgeous display. Of course, just at present it is practically empty, but an earnest of what was to come was seen in the thorough preparation that the beds were undergoing. The design is for the maintenance of its character strictly formal, and this is still more accentuated by the style of planting that is adopted. No mixing is allowed, but masses of distinct colours are formed with various suitable plants, which must obviously be provided in enormous numbers. The whole garden is sunk beneath the normal level, the sides being of closely mown thick turf. There are a few clipped shrubs here and in other parts of the garden, but these are not sufficient in numbers to form a feature or to warrant any reproach as to mutilation. To the right of the garden, as seen in the photographic illustration (fig. 46), is a long conservatory-like corridor stocked with large Palms. This structure has seen at least three changes, for, while originally erected for plants, it subsequently became a theatre, and has now been reconverted to a plant house.

A strikingly handsome system of planting large beds is adopted, and it is a method that cannot fail to meet with general appreciation. It has been very strongly advocated from time to time in the pages of the *Journal of Horticulture*, and consists in having huge masses of one kind of plant conspicuous for its foliage or the colour of its wood or its flowers, as the case may be. Nowhere better than in an estate of the magnitude of Blenheim could the method be exemplified, and the clumps of Golden Yew, *Prunus Pissardi*, and Golden Privet, to mention three only as examples, are splendid. Seen from a distance, the rich yellow of the last-named looks like a sheet of gold, while closer approach shows the dark stems of the *Prunus* in the foreground. In various suitable positions these are found, and in each instance the effect striven for has been secured. At no one time are the whole of them at their best, but they follow in rapid succession to form the cycle of the year. The American Garden, of days gone by, with its *Rhododendrons* and *Azaleas*, has now been almost exclusively planted in the manner described.

The lake is a magnificent sheet of water, which was, as Mr. Jefferies has already stated, thoroughly cleansed some time back. Its banks are clothed in verdure, trees and shrubs making permanent ornaments. It is near its margins that are seen some splendid Cedars, and here and there a *Taxodium distichum* rears its stately head. Even now before the buds have expanded this portion of the pleasure grounds is most charming though not so much so as when the trees will all be bursting into leaf or later when the tints of autumn herald the approach of winter. Thousands of Daffodils are pushing through the grass of the banks, and will ere long adorn the green carpet as with a cloth of gold. This is a most commendable practice, and one that, though it is growing in popularity, ought still to have considerably more attention. One of the attractions that has yet to come is now being established, and consists of the establishment of a collection of the best hybrid *Nymphæas* in the shallows of the waterside. These, it is confidently anticipated, will eventually make a superb display, though we question if it will ever be more imposing than the masses of white Lilies lower down the expanse of water.

Travelling now along the banks, crossing the water at one place, passing the cascade and re-crossing, we proceed again towards the gardens as distinct from the pleasure grounds. This is no short journey or an easy one, for slopes of sharp gradient have to be negotiated and winding paths of grass and gravel to be followed. A Rose garden *en route* claims a brief glance in passing, and its hundreds of plants would certainly produce an enormous number of flowers, but for one thing. It is unfortunately encircled by large trees, and, these being in close proximity, must send their roots beneath the Roses and rob them of food while the branches above will deprive them of light and air, that Roses, of all plants, appreciate in abundance. This will militate against the best success, which is a matter for regret when such care has been taken in the planting of good stock. Teas, Hybrid Teas, and Hybrid Perpetuals are all largely represented by the best varieties. In another position, an arch of Crimson Rambler and Clematis has been formed, which, when the plants are established, will be a gorgeous sight.

A few years back, during the time of the late duke, the collection of Orchids was one of the most renowned in the kingdom, and when, some six years ago, the stock was sold it became distributed throughout the length and breadth of the land, to the enrichment of many an orchidist's structures. In those days house after house contained nothing but Orchids—not in ones or twos but in hundreds of a kind. To-day, though Orchids are present, it is in comparatively limited numbers, other plants calling for a share of attention. This is, perhaps, better. At any rate, it lends wider interest to the place, for whereas in bygone days only the Orchid enthusiast felt at home, the general plant lover may find abundance to interest him in Blenheim gardens.

Carnations everywhere is the conclusion reached when the houses and frames have been seen. These plants are grown in thousands, and are represented from the cutting in a "thumb" to the specimen that requires a 12-inch pot for the accommodation of its roots. We look in vain for signs of the dreaded disease, and, needless to say, Mr. Whillans has no wish that it should visit Blenheim. There are flowers in numbers on the healthy plants, and Duchess Consuelo, the handsome yellow, is practically always in flower. Closely following the Carnation for popularity come the Roses, of which about 3000 plants are cultivated in pots, and rarely, indeed, can such a collection be seen in a similarly excellent state of health and cleanliness. Flowers sweet in perfume and rich in colour are always to be had, and, of course, during the winter months find high appreciation. Naturally enough all kinds of plants are cultivated, and almost invariably in large numbers, but it is unnecessary to give details of them. However, the Cyclamens are worthy a special note, as they are so magnificently flowered and carry splendidly marbled leaves. Chrysanthemums, too, in the infantile stage are abundantly in evidence, and will do their share towards the floral display in the autumn.

Other structures are necessarily devoted to Vines, Peaches and Neectarines, Figs, Melons, Cucumbers, Tomatoes and Kidney Beans, and in each instance it is easy to see that sound cultural methods are adopted. Under no circumstances could the importance of scrupulous cleanliness be better illustrated than by a visit to Blenheim Gardens. It will there be found to reign supreme over everything, and to this fact doubtless may largely be ascribed the excellent state of health which shines forth in all plants alike, whether they be grown for their foliage, flowers, or fruits. Not only within doors is the fruit eminently satisfactory, but also on the walls surrounding the gardens. These have almost wholly been clothed by the present garden, and with the exception of a few very old trees they are well nigh perfect. The wood is clean and sound, and such as may reasonably be expected to give remunerative returns to the grower. The vegetable garden, which covers an area of about 12 acres, is not stocked as it will be later in the year, but it is a department that is accorded the same attention as is given to all the others. Broad borders of herbaceous plants cross and recross the garden, and will adorn it with brightly hued flowers throughout the major portion of the year.

Though it cannot be said that all the features of Blenheim have been adverted to, it is necessary to draw these notes to a close. There are many other aspects equally meritorious that could, and perhaps ought to have been incorporated; but these must stay for a later day. The bothy, for example, is a model structure that alone is worthy of description and illustration if space were at command. Now we leave them, as we found them, in the care of Mr. Whillans, to whose industry and energy the estate owes so much for its present interest and beauty. It is a palatial home, and it is pleasing to be able to place on record that the efforts of both the Duke and Duchess of Marlborough tend not towards its maintenance alone, but also to its improvement.—H. J. WRIGHT.

APPLES FOR PERTHSHIRE.

IN a county so large in extent, so diversified in physical features, and presenting such a variety of soils as Perthshire, it is obvious that there is ample scope for the selection of varieties of Apples for cultivation. In the rich alluvial soils which prevail in the lower valleys Apples are extensively grown, and where intelligence is exercised excellent crops are obtained. This, however, is the exception, not the rule, at present in the once famous orchards in the Carse of Gowrie.

During the past two decades, or probably longer, the trees, with a few exceptions, have been left to take care of themselves, cutting out a dead branch here and there being the only pruning (if such it can be called) which the trees get, while manuring is unknown. The trees are old and debilitated, and in consequence of pruning being neglected are much overcrowded. This further impairs the fruitfulness of the trees by excluding the sun and air, thereby leaving the wood immature and liable to be destroyed by frost. Many of the varieties are also inferior, although there are some—such as Irish Green, Tom Montgomery, Catshead, and Winter Strawberry—which do well in favourable seasons. Lass o' Gowrie seems to be admirably adapted to the heavy clay soil of the Carse, and is probably one of the most profitable market varieties. It is an attractive Apple, and when not too ripe is of good quality, and always commands a high price. Many of these old-fashioned sorts have by lack of cultivation degenerated into mere Crabs, and the best thing that can be done is to have them displaced by modern varieties which are known to succeed satisfactorily in the locality.

There is no doubt that Apple culture, intelligently carried out, can be made a remunerative branch of farming in Perthshire. If the farmers would display similar sound judgment and common sense regarding fruit culture to that they do in the cultivation of cereals we should soon have abundance of fruit of the finest quality. The soil and the climatic conditions in many parts are favourable to fruit farming; all that is necessary are men educated in the most approved and practical methods of cultivation.

In commencing Apple culture the selection of a site for the orchard is the chief consideration. That which has a southern exposure should preferably be sheltered from the north and east winds, but not too much enclosed by trees. A low damp situation must, if possible, be avoided, as trees growing in such a position are liable to be injured by late spring frosts. Therefore a slightly rising ground is to be preferred, although many orchards in the Carse of Gowrie are only 25 feet to 50 feet above sea level.

Only varieties which have been tried in the district and proved satisfactory should be selected. We do not think it advisable to plant a large number of sorts, and would restrict the list to those that are of excellent quality and also productive. It is much more profitable to grow a dozen reliable sorts in quantity than three times that number the greater proportion of which produce nothing but leaves. Pruning should be systematically carried out from the start, keeping the main branches widely apart so as to admit a maximum of sun and air, without which well matured wood cannot be obtained. This is a matter of vital importance, as without thoroughly ripened wood sound Apples of high quality will not be produced.

Close-spur pruning, excepting in the case of one or two varieties, produces the most satisfactory results, after the trees have attained to fairly large dimensions. In a young state, root-pruning may have to be practised to check over-luxuriant growth and to bring the trees into a fruit-bearing state. After they have come into full bearing heavy mulchings of farmyard manure, annually, will prove beneficial.

The following have been tested in various localities and have proved free-bearing under orchard cultivation in the form of dwarfs and half-standards. Varieties for culinary purposes—Alfriston, Annie Elizabeth, Wellington, Ecklinville Seedling, Hawthornden, Lord Suffield, Stirling Castle, Warner's King, Tower of Glamis, Keswick Codlin, Cellini, Lord Derby, Lady Henniker, Bramley's Seedling, Lane's Prince Albert, Beauty of Kent, Manks Codlin, and Potts' Seedling. Regarding dessert varieties a smaller choice is at our disposal, still there are several first-class sorts which succeed admirably, such as Irish Peach, Worcester Pearmain, King of the Pippins, Court Pendu Plat, and Lady Sudeley.

In numerous private gardens throughout Perthshire the cultivation of the Apple is extensively and successfully accomplished. The trees are grown as dwarfs in the open garden, espaliers, cordons, fan and horizontally trained trees on walls. Under these varied forms beautiful and high-class fruits are produced if varieties such as Duchess of Oldenburg, Peasgood's Nonesuch, Bismarck, Golden Spire, Grenadier, and Rymer are chosen. Several dessert Apples are benefited by being grown on walls, notably Ribston Pippin, Cox's Orange Pippin, Red Astrachan, Kerry Pippin, Devonshire Quarrenden, and Fearn's Pippin.—WM. LITTLE, *Bridge of Earn*.

PHALÆNOPSIS MRS. J. H. VEITCH.

THE *Phalænopsis* that was shown at the Drill Hall on Tuesday, 14th ult., under the name of Mrs. Jas. H. Veitch, by the Chelsea firm of Messrs. J. Veitch & Sons, Ltd., was very distinct and peculiar in structure, as may be gathered from a glance at the woodcut (fig. 47). It is a hybrid that resulted from a cross between *P. Ludemanniana* and *P. Sanderiana*, the former being the pollen parent. The sepals and petals are about three-eighths of an inch in width, and are yellow with a tinge of green, and covered with numerous crimson brown spots. The small lip is white on the front lobe, with pale yellow marked with crimson purple at the base; the side lobes are white with

FIG. 47.—PHALÆNOPSIS MRS. JAS. H. VEITCH.

stripes of a similar colour to the base. The Orchid Committee of the Royal Horticultural Society recommended an award of merit.

NOTES ON PHAIUS.

THERE are many lovers of Orchids who have not a house to devote to their culture, and to those who desire plants that will thrive in a miscellaneous collection, *Phaius* must be recommended. They are, with one or two exceptions, of easy culture; they have noble foliage, and carry stately spikes, and even when not in flower are ornamental. It is not of the species that I wish to speak, although all will repay the attention bestowed upon them, but of the hybrids raised from *Phaius tuberosus* crossed with the East Indian forms which, thanks to the skill of the hybridiser, combine the beauties of the two parents.

First we have *P. amabilis*, which is a hybrid between *P. grandifolius* × *P. tuberosus*. It has white petals tinged with rose, and a claret coloured lip. Then comes perhaps the most beautiful of all, *P. Cooksoni*, which resulted from crossing *P. Wallichii* with *P. tuberosus*, and is intermediate between the two parents. *P. Marthæ* is a hybrid between *P. Blumei* and *P. tuberosus*; it is a most beautiful variety. The new *P. Normani* shows considerable variation, but all the forms are valuable, especially some of the yellow ones. *P. Sanderianus* and *P. tuberosus* were the parents.

When in active growth *Phaius* delight in abundance of heat and moisture, but when at rest they may be placed in a cooler house, and much less water will suffice. The compost I find them succeed well in is two parts of loam, one part of peat, with pieces of crocks about the size of hazel nuts, and a fair sprinkling of coarse sand. They may be propagated by division, but whenever they are repotted great care must be taken not to give any water till the roots get well hold of the compost, or the young growths are apt to decay. When growing vigorously a little weak liquid manure will do them no harm.—J. BARKER, *Hessle*.

THE FUTURE OF ORCHID GROWING.

JUDGING by precedent, the time must come sooner or later when our favourite plant, the Orchid, will be elbowed out by some new candidate for public favour. From being the aristocratic flowers grown only by those with long purses, they have become everybody's, and

anyone who can afford to build even the smallest glass house can, with little outlay, stock it with some of the finest, though commonest, of Orchids. On the other hand, the enormous prices that have recently been paid for novelties show that, while appealing to the latter class of cultivators, Orchids have not lost their hold upon the wealthy.

A healthy sign of the times respecting the future of Orchids will be found in the fact that in place of the botanical curiosities and rarities many of the leading growers are finding out the best species and varieties for decoration and cutting, and are cultivating them at the expense of the former. Our market growers are purchasing and collecting Orchids largely to meet the ever-increasing demand for the flowers when cut, while many of the florists' shops are now gay with gorgeous Cattleyas and other showy kinds.

In short, the Orchid is recognised as one of the loveliest plants in cultivation, and it will no doubt be grown in increasing numbers for its intrinsic worth, for its delicate beauty, its lasting powers, and its other good qualities that make it second to no other. Then Orchids are so distinct from every other family of plants that a child can pick them out. They have a quaint form, wonderfully diversified, but easily known through all its variations; the features of each individual kind are distinct, yet each present the same beautiful structure, and the texture of most of them is very delicate and beautiful.

In the future, again, there is no doubt that numbers of the fine hybrids now appearing will be largely grown for cutting. Most of these plants have a decidedly stronger habit than the species they have sprung from, and this, of course, will render them more useful for the purposes of decoration of all kinds. Take the deciduous *Calanthes*, for example. The true species and varieties are few in number, but there are already scores of hybrid forms, and they are being added to daily, each one a charming garden plant flowering at the dullest season of the year, and producing a quantity of blossom far exceeding that given by many other plants of similar size.

Hybrid *Dendrobiums*, again, are among the most beautiful of plants at this season, and no one can fall out with growing such a hybrid as *D. Ainsworthi*, for instance. One of the oldest, it is true, but still one of the best and freest flowering kinds in existence. The *Cypripediums* raised artificially are more numerous than either of the preceding, and extremely useful for cutting owing to the length of time they last either on the plants or when cut. *Cattleyas* and *Lælias*, though less numerous as yet, are being rapidly added to, and scarcely a week goes by without something new being added in one section or the other.

But we need not trust to hybrids alone for good garden plants, for the number of useful species is very large and varied, and there would be little trouble in selecting sufficient to keep up a fine succession of flowers the whole year round. This being so, and the fact that nearly every genus contains at least one species that is cheap, showy, and easily grown being considered, there is little doubt that, just as small collections have sprung up within the last few years, their number will be still further increased, and really the popularity of any plant is better assured when it is grown by a number of small cultivators than when, by its rarity and high price, it is confined to the few. There is an increasing demand for cheap, yet showy and beautiful Orchids, and this will not, I think, diminish even should the wealthy patrons of the cult become tired of paying their hundreds for rare and unique kinds.

—H. R. RICHARDS.

A MEMORY.

As an old amateur correspondent of the *Journal of Horticulture* for more years than I care to count, contributing a special article to accompany my picture in the "Veterans' Portrait Gallery," I propose to give a few personal reminiscences of Dr. Hogg, which will probably be of general interest. Although having had the privilege of making the Doctor's acquaintance early in the sixties, it was not until 1876 that the writer was fortunate enough to secure a visit into Herefordshire of this eminent pomologist, which was repeated on several occasions in connection with the exhibitions of Apples and Pears, which were held during 1876 and 1885, mainly for the selection of typical varieties, for reproducing in plates and sections in that standard work, "The Herefordshire Pomona." It is needless to say, without the valuable aid of the talented author of the "Fruit Manual" as technical editor, that valuable publication could not have taken up the position it is credited with as *the Pomona* of the century.

While in Herefordshire, Dr. Hogg, as may be supposed, took the greatest interest in the old extensive orchards throughout the county, and much regretted the neglected state into which most of them had fallen, making many valuable suggestions for their recuperation. Several varieties now in commerce he named, and brought into notice

especially the Herefordshire Beefing, and he was greatly struck with the rampant growth and luxuriant cropping of that excellent variety Braddick's Nonpareil, generally unknown and unvalued by the farmer.

Although not a personal speciality, Dr. Hogg always gave the prestige of his name and paper (is it not rightly called the Rose journal?) to the interest of the Queen of Flowers, while, although closely connected with the "Herefordshire Pomona" as Chairman of the Fruit Committee, and author of the two papers "On the Orchard and its Products," I have never failed in allegiance to my first and earliest love for the Rose, as instanced by assistance rendered in starting and resuscitating the National Rose Show, and inaugurating the West of

FIG. 48.—THE REV. C. H. BULMER.

England Rose Show over thirty years ago—an edifice on no broken column, but a pillar of strength and green old age.

It is, indeed, a privilege to have shone, how dimly so ever, under his reflected light; to have moved in a quiet and uneventful, but I trust not altogether useless orbit, in that restful and yet invigorating, promising (unless through one's own fault), seldom disappointing, devotion to Nature, and to deciphering, one by one, her secrets, as a lifelong labour of love and patience. There, with many other kindred souls reposing, as the shadows gradually lengthen—quicker far, as the goal is approached—I stand, awaiting the call to enter that fair haven where there are no shadows—no night to follow on eternal day.—C. H. BULMER.

PICTURESQUE GARDENING.

SELDOM, one thinks, is the higher enjoyment of "the purest of human pleasures" attained until the bonds of formality are loosed which restrain the ministering hand from aiding and abetting the careless grace and happy abandon of Nature. Our theme is no new gospel, yet it is one that has been neither too widely preached nor extensively practised. Trimness and tidiness are fatal to its development; geometrical precision is its abomination. Kitchen gardening is eminently practical, flower gardening pleasurable, but the third great phase is one which appears to bring humanity into a closer communion with the great kingdom of silent life; hence, I take it, is, in a sense, the greatest of them all. Let it not be understood, however, that any intention is present of praising the one to the disparagement of the others. Each and all have, of necessity, their own place in the fullest expression of gardening art, forming a trinity of utility, beauty, and natural grace, leaving nothing to be desired.

Here and there, in some fine old ancestral demesne, evidence is not wanting of the presence of a spirit of freedom, but, again, many there are in which it is almost conspicuous by its absence. There are no rules to guide the hand of the planter, or hard and fast lines to circumscribe its possibilities, for these are, indeed, boundless. To the student of Nature only is given the keynote of natural harmony, with power to transcribe to unwritten pages her most satisfying symphonies. It is easy to gather from all sorts and conditions of

places in the gardening world sufficient outlines to form not only an ideal picture but a possible one. Wandering last summer through the unkept portions of an old domain, and following the course of a streamlet to where it tumbled into a Bracken-fringed pool, it came as a surprise to find some dozen pure white spathes of the common Calla springing through the handsome foliage in their water bed. Thus treated the Calla is a unique plant for the position, but rarely seen. Hardest of the hardy, which does not seem to be generally known, or one might wonder that its claims are not oftener recognised. A mile away, in the same demesne, a miniature lake where once that yellow-buttoned vagabond Nuphar lutea reigned supreme, its aristocratic cousins, Mons. Marliac's beautiful hybrids, worthily hold the position; and, judging by fine specimens of *N. chromatella* and *N. rosea*, appear to be well able to hold their own. It is needless to compare the happy surroundings of these lovely Lilies with those of the tank, tub, or formal fountain to which they are too often relegated, yet scarcely superfluous to point out some of the bye-ways into the kingdom of picturesque gardening, by most of which admission is practically free.

Taking an annual peep, in late summer, into an old fashioned garden, where all is not only done decently and in order, but well done, it is astonishing to see how the Torch Lilies, *Tritoma Uvaria grandiflora*, have usurped space in the herbaceous borders to the detriment of lesser things. If wishes had wings, fain would one fly with them to the bare banks of a fairly extensive lake near at hand, which, to me, seem always hungering for their company. As the shuttle of thought flies through the loom of memory comes back a feature of one particular place where a pretty pond in the foreground of the shrubberies was adorned on the one side by a bold grouping of Tritomas. The glow of the torches, in their season, duplicated by reflection in the water, left no question as to suitability of position. It was veritably the plant for the place, and the place for the plant. Yet impressions of failures are second only in value to those of success, and possibly more educational. Probably the above happy results were accidental, for on the opposite bank the same planter had dotted a number of *Arundo conspicua*, like "Daisies all of a row." It had been done designedly, doubtless, and so had the Tritoma planting, but here no design was apparent.

Work without design must perforce bring many unfortunate illustrations into a chapter of accidents, and the best book of design of which I know is that whose impressions are deeply graved by a life's observation. It teaches one to know his prerogatives, feel his power, and admit his responsibility as a subject under the imperial dominion of Nature in the kingdom of picturesque gardening. Knowing, feeling, and admitting such, he will rarely err or fall short in the labours of love. Every vantage point, from the top of a crumbling wall to the depths of a dell or dingle, is suggestive. One looks at a bare, unlovely, loose-topped wall, and feels ashamed of its nakedness. Heigh, presto! and over many years and many miles memory brings back such another, but partly clad in a thick glowing coat of *Erinus alpinus*. Of such is the beauty of fitness of thing to a purpose; the same plant in bed or border being insignificant in its humility.

Meek Alpines, bold Gunneras, feathery Arundos, quaint Irises, Sumachs, and such plants as crown the dying year with a glory of crimson and gold, each seem to adapt themselves to certain positions, which not only enhance their beauty, but is duly reciprocated in their surroundings. A host of tangling, twining, trailing plants, ever trying to escape from the bondage of tie and trellis, on the one hand; gnarled and naked tree stumps, crannied cliffs, old bridges (and new ones) on the other; all waiting for the ministering hand to bring them into happy union. Infinite variety, endless interest, surpassing beauty, all such good things are provided for those who enter into the kingdom of picturesque gardening, where shears and prunings cease from troubling, and weary gardeners are at rest.—E. KNOWLDIN.

CAMELLIAS.

I READ recently in one of the horticultural publications the following words:—"Mr. Wm. Paul does not share the general impression that this fine old plant is as dead as Queen Anne (commercially), or he would not continue to devote so much space and attention to it." No, my friend, no; I do not share that impression. The Camellia is not even "commercially" dead, but living and influencing (if in a small and select circle) in the full enjoyment of life, waiting until the foolish fantasies of fashion shall be corrected, and transformed by taste and reason. If flower hawkers and fashion seekers look upon it with disdain, there are those still living who love and cherish it. I have faith in the past, present, and future of these lovely evergreen shrubs or trees, for trees they will grow into if given the necessary space for

tree development. It is true that there are fashions in gardening as well as in other things, and it is well that it is so, for as a sequence many bright and beautiful things are brought within our view. But few of us follow all fashions, and I certainly should not think of following a fashion which ignored the most beautiful of all our easily cultivated flowering evergreens.

Then as to change. The mind of man is so constituted as to delight in change. Even in this dull climate of ours, after much sunshine we delight in shade, after a long spell of dry weather we delight in rain. But the change should either bring joy to our senses by the uprising of equal or superior beauty, or comfort to our hearts by the reflection that it is a blessing in disguise. With their permission I would ask my fashionable friends whether all the fashionable flowers which have supplanted the Camellia in recent times surpass or equal it in beauty or usefulness. From November to March, all through the winter months, one has from these almost hardy evergreens matchless foliage and a succession of flowers of almost unsurpassable beauty.

It has been said that the Camellia is difficult to cultivate. In my opinion, however, it is as easy to grow as a Laurel, a Laurustinus, or a Sweet Bay. But it is not hardy and should not be grown out of doors except in the south or west of England, or elsewhere against walls at the seaside, or in other favourable conditions of soil and climate. Few *Journal* readers can require instruction from me on cultivation, but to those few I may say, Grow Camellias in turfy loam or turfy peat and old cow manure, with sand if the loam be of close texture. Prepare the soil well in advance. In potting press the soil very firmly round the roots, but do not hammer it down into an impenetrable mass. The plants should be freely watered when flowering, and even more when growing, with very careful and moderate supplies at other times. Drainage should be perfect. A low temperature, but over 32°, is desirable in every month excepting April, May, and June, when 50° to 60° by night, and 60° to 75° by day, with shade during the hottest part of the day, are most suitable.

FIG. 49.—MR. WILLIAM PAUL.

Syringe freely when in active growth. Prune fearlessly in autumn if the plants become mis-shapen, but do not cut back if you can help it into older than one or two seasons' previous growths. Never mind sacrificing a few flower buds when pruning. At the end of June remove the plants to a north border where they get only the early morning sun, and let them remain there during July, August, and September. Reconvey under glass at the end of September, merely excluding the frost unless early flowers are wanted, when more or less heat may be employed.—WM. PAUL, *Royal Nurseries, Waltham Cross, Herts.*

LOOKING BACKWARD.

IN the late "forties" I see myself entering the gardens of my father's employer, a large cotton manufacturer, at a place twelve miles N.E. of Manchester, and on the western slopes of the Pennine range which forms the backbone of England. Gardening was not the proposed avocation mapped out for me by my parents. My father, who was the accountant of the works, had intended training me up to his profession, so that eventually I might be able to take his place. A severe illness, caused in large measure by too close indoor confinement, induced my parents to alter their plans, and, in consultation with my master and mistress, who always took a special interest in me, brought about my admission into the gardens.

I had always, from my earliest years, had a taste for gardening, from the time I grew my first pot plant—a Musk—in an old cracked teapot of my mother's, and pruned her pot Rose so effectually that, as she ruefully, but laughingly said, "It must be well pruned, for there is only the stump left." The gardener I was put under was one of the good old-fashioned type—a Yorkshireman, essentially a practical man. He was one of the best men I have ever seen with all gardening tools, and specially with the spade. He was no book man—he rather scoffed at writing gardeners; but he was the best herbaceous plantsman in our neighbourhood, and a florist of the old school whose favourite flower was the Pansy. He taught me how to know a good flower when I saw one, and as to shrubs of all kinds, evergreen and deciduous, his knowledge of them was like Sam Weller's of London, "extensive and peculiar" and thorough.

Being always a reader, and a frequenter of the booksellers' and newsagents' shops somewhere about the beginning of the "fifties," I made my first acquaintance with the then *Cottage Gardener*, and from it I got visions of a larger world of gardening than up to that time I had any idea of. I read each weekly number from first page to last. I read them again and again, and the writers' personalities became clearer to me each week, so that Robert Errington, Donald Beaton, Robert Fish, Thomas Appleby, and others became my personal friends with whom I held converse week by week, and to whom I looked up with the reverential awe of a young hero-worshipper. My first communication to the *Cottage Gardener* was somewhere about the year 1854.

In 1856 I came into Nottinghamshire to be gardener to Mr. William Sanday, the great Leicester sheep and Shorthorn breeder, and my facilities for advancing in gardening were there strictly unlimited, the encouragement to go on to higher things was of the heartiest, and through all these years I occasionally dropped notes to "our Journal," generally under the pseudonym of "Excelsior" or my own name. I have stayed in the county all through, the last twenty-six years with my present employer, Mr. Frederick Wright, J.P., of Lenton Hall, Nottingham. Notts is a county, I consider, good enough for any man to live in, and its beautiful county town, or city now, is one which draws out daily more and more my admiration and love. My later writings as "An Old Provincial" will speak for themselves.—N. H. POWNALL, *Lenton Hall Gardens*.

P.S.—After concluding the writing of these notes the *Journal* brings word of the death of one of the most valued contributors of the "sixties and seventies"—"Wiltshire Rector." He was one of those writers whose gentle spirit put such a charm into all he wrote, and whose "gay wisdom" enlightened his words, and drew to him the love of readers of all degrees of gardening life. It is no disparagement to the other writers of the time to say that he was the first to be read as soon as the *Journal* was opened. We are the poorer to-day by his death, and I am sure we shall all unite in saying, 'Make him to be numbered with Thy saints in glory everlasting.'—N. H. P.

MODERN VEGETABLES.

WHILST we find seedsmen's lists overcrowded with the names of new varieties, or selections, of diverse vegetables, we have to look for distinctions and improvement in actual growth. But the modern development of vegetables, if slow, has been sure, and if the variations or improvements have been slight, yet have they been invariably progressive. It is difficult to define the advance seen in the novelty of this year, as compared with that of last year, but if we compare the best latest with the best of twenty years ago, then is the advance most marked. How specially this is so is well evidenced at our exhibitions, when collections of vegetables are staged, showing not only the highest of existing excellence in variety, and also the highest art of the cultivator, but even also the most advanced taste in setting up or in arrangement; so that whilst a fine collection is a work of taste in display, the production is a work of art in culture, and the superb variety is the evidence of long work in cross breeding and in selection.

We have in these modern days such splendid products that it is only natural to ask whence can come, or in what form will come

other improvements. Most certainly they can be only infinitesimal if for no other reason than that existing products are so superior that little room for advance remains. To what an extent have garden Peas developed. The old round whites and blues, hard and flavourless, and not great croppers, yet to our progenitors valued varieties, are fast passing out of cultivation, more because there are so many of the richer flavoured, sugary, wrinkled Marrows to supply our needs. We have delicious wrinkled varieties for our earliest as well as for our latest needs, and for all the long season. We have the dwarf, medium, or tall in height, and in every case of the finest excellence. What beautiful pods are now seen on exhibition tables, how long, well filled, green, and of the most perfect form and high flavour. No mere large pods will pass muster now, because there are such splendid varieties that are fitted for the table of the gourmand, and are equally at the command of the poorest.

What a change has been effected in Cauliflowers too, and with the help of the dwarf earlies and of the late giants we can have these for consumption and for exhibition for a long season. How solid are the heads now, how white, how easily produced, and how fine and effectual are they on the exhibition table. A generation ago no one could show such Cauliflowers, and for so long a period, as gardeners now can.

Few vegetables exhibit development more markedly than does the Onion. The Liliputians of older days have become the Brobdignagians of the last years of the century. No longer are bulbs weighed by ounces; they have become so big that their weight is counted by pounds. Ailsa Craigs, Records, Exhibitions, Lord Keepers, Ne Plus Ultras, Excelsiors, and many of others, vie one with another—that is if they be distinct—in producing, under what are also modern conditions of culture, bulbs that are not only of marvellous dimensions, but of

FIG. 50.—MR. N. H. POWNALL.

remarkable beauty in form and of matureness and solidity. Truly we seem to have reached in Onion production to a point beyond which it is difficult to pass.

But whilst even the few things named serve to show how much the modern cultivators excel the old growers in productive skill, just as the products themselves show their great advance on earlier ones; none shows this advance in variety, and in culture, as does the Tomato. Here we have a product that has leaped from comparative worthlessness into marvellous popularity, and is now one of the most valued of highly cultivated vegetables. Not a gardener in the fifties could have dreamt of the popularity in store for the Tomato,

and the new labours and duties its culture would cast on those whom we now term modern gardeners. What a bound has been evidenced in the change from the old coarse and sutured forms to the perfect and beautiful fruits of to-day! What crops do our modern ones produce! How wonderfully are they consumed as ordinary edible fruits! The supply, so good, so improved, so attractive, so superior in every respect, has tempted humanity to partake of them, and thus created the demand.

We may turn to our Beans, and find in the Runner or climbing section much striking development. Not of the old, short, thick, and too soon ageing pods of earlier days, but produced in great abundance—long, handsome, tender pods of the highest excellence, and giving in length and productiveness double the crop produced by the old strains. In Longpod Beans our Exhibitions, Leviathans, and Seviles are unrivalled, and in even the Dwarf Kidney race there is advance in quality and pod production every year. In Carrots, in Beets, in Turnips and Radishes, in Cucumbers also, the advance has been continuous and of the best.

If there has been no appreciable addition to the quality of the Potato tuber, there has been material advance in productiveness. Main Crop, Up-to-Date, The Crofter, Ellen Terry, Pride of Tonbridge, Challenge, Snowball, Windsor Castle, Reliance, and many others testify to the wonderful tuber productiveness of modern Potatoes. We have seen in Cabbages, with undoubted development in quality, rather a recession in quantity, as the modern taste now favours smaller but much tenderer and more precocious varieties than were formerly in most favour. Even Spinaches are superior now to older varieties, and in Longstander and Victoria distinct superiority over the old Flanders is found.

But whilst during the past two decades improvement in kinds through superior varieties has been marked, we have seen very few additions to our already considerable list of kinds suitable for consumption. The most noteworthy is the Chinese Artichoke, or *Stachys tuberifera*, for the tuberous *Oxalis crenata*, pleasing as it is, can hardly be classed as a new vegetable. However, we have grand selections, triumphs of patience on the part of raisers and seedsmen, whilst gardeners by their skill in culture have done their part worthily also in the great work of vegetable advancement.—A. DEAN.

THE AURICULA.

So many people write to me about the Auricula, and I have concluded that a few words in the *Journal* may be useful. The Alpine Auricula—seedlings and hybrids from *Primula pubescens*—is the easiest to grow. They make splendid rock garden plants, or as isolated specimens in the front row of herbaceous borders. A rich deep clayey loam suits it best, and if it is moist all the better, as the plants dwindle away if grown on shallow, light gravelly soils. The finer varieties are grown in pots, and they are beautiful when in flower. All that they require is a cold frame, and the plants must not be very far removed from the glass, or the leaves and flower stems will become drawn. This is avoided by removing the lights altogether whenever the weather is favourable; and as none of the true Alpines has mealed foliage a shower of rain is beneficial, though of course small plants in flower pots would be injured by long continued rains, and I do not like them to be exposed to rain at all during the late autumn and winter months. The flower trusses begin to show early in March, and the blossoms appear from the middle to the end of April. I have had them in flower well into May by keeping the plants in a frame on the north side of a high wall. I showed a small collection at the Tempis Show last year in May; but as the great northern Auricula grower, the Rev. F. D. Horner, aptly remarked—

“The Auricula in May
Has had its day.”

And truly we do not want it in flower with the Tulips, as happened last year, for in the same tent with my simple Auriculas were the gorgeous cups of the show Tulip.

The pot culture is very simple. The compost for both Alpine and Show varieties should be four parts of good yellow fibrous loam, one part of decayed manure, and one part of leaf mould, with a little sand if necessary. I often wondered how the old growers managed to keep life in their plants, with the rich compost they prepared for them, until I read Emmerton's book, wherein he is very particular in insisting on the potting materials being mixed two years before using, and it was to be well turned over frequently in the course of the twenty-four months, therefore the washing and bleaching must have pretty well taken the fertilising properties out of the goose manure, the sugar baker's scum, the blood manure, and other unwholesome ingredients. Here is the recipe of Mr. Isaac Emmerton, the celebrated Auricula grower:—Two barrowfuls each of goose manure steeped in bullock's blood, sugar-baker's scum, night soil, and fine yellow loam.

That is six barrowfuls of strong manure to two of loam. It would undoubtedly require a considerable amount of turning and exposing to summer's sun and winter's frost.

The Show Auricula is divided into four sections—the green edge, white edge, grey edge, and selfs. The green-edged varieties always have green leaves without meal or farina on the foliage, but the others may have green or mealcd leaves, and certainly some varieties have very beautiful foliage, so densely coated with fine powder as to be quite white. There is more care required in growing Show Auriculas, as

FIG. 51.—MR. JAS. DOUGLAS.

they will do no good planted out, but always require the shelter of a frame. They are propagated by offsets, which take from twelve to eighteen months to grow into a flowering size. They require some care in the offset stage, and it is better to leave them on the parent plant until they are rooted. Drain the pots carefully and pot firmly, keeping the plants down to the fresh leaves, as they are apt to produce long bare stems. The largest flower pots used ought not to be more than 5 inches in diameter for the very strongest growing varieties.—JAS. DOUGLAS.

— MUSHROOMS.—It is not often that growers of Mushrooms give instances of failures, because perhaps their relation would, to them, appear to convey some technical errors that are not creditable. It is rarely that the stables are blamed for partial or complete failures, but it is, nevertheless, a fact, that some can be traced thereto. Horses, and especially those under preparation for hunting, are given drugs, which are directly responsible for failures in Mushroom beds when such manure is collected. I have proved this very clearly this season, one bed made under those circumstances producing very few Mushrooms, so few, indeed, that its retention was not considered profitable. Its removal satisfied me that the course was the right one, as no signs of activity for present or future bearing were apparent. Beds made later when the horses were fed on natural food only have given regular supplies, the treatment of the manure in preparation being the same, their after attention identical, and the same house accommodated them. It is generally known that manure from horses medically treated is unfavourable for Mushrooms, and it is well to inquire when a course of medicines is being submitted, so that the manure then can be otherwise employed, and thus save labour and disappointment, which is almost certain to arise.—W.

CULTIVATION OF CELERY.

SWEET and nutty Celery is regarded as indispensable in the majority of gardens. The season for its use extends from September to April, but if the demand is great, or the culture of the crop not carried out in the best manner, the supply usually runs out at Christmas or soon after. On strong retentive soils Celery is liable to decay, hence when grown on ground of this character protection must be afforded the plants from excessive damp and frost, especially that intended for late supplies. This can be done by nailing together two boards at right angles, forming a V-shaped cap or protector, which can be readily placed on or taken off as necessary. Temporary protection is afforded by a light covering of dry litter or bracken. If this remain on for long in wet weather it will do harm.

Seeds for furnishing plants for the main crop must be sown in March or at an early date. It is best to sow on the broad surface afforded by a pan or box, so that the seed may be distributed thinly and seedlings raised of a sturdy character, these being more easily handled when the time for pricking off arrives. Drain the bottom of the pan or box well with crocks, and put over that the rougher parts of the compost. Then fill with a compost of rich fine soil mainly consisting of loam, manure, leaf soil, and sand. Make the surface fine and level, and give a good watering with hot water through a fine rose. When the soil is thoroughly drained sow the seeds evenly and moderately thinly, dredging a layer of fine soil as a covering. The best position for the seed pan or box is in a temperature of 58° to 60°, or on a mild hotbed in a frame. Cover the soil with a pane of glass and paper to prevent rapid evaporation and consequent drying of the soil.

Celery takes two or three weeks to germinate, hence it is important to maintain the soil in a uniform condition of moisture. Should the surface soil become dry it may be moistened by dewing it over with the syringe in preference to heavier watering with the rose. After germination the seedlings require warmth, moisture, and light, and when well established a light airy position in a cool structure. This treatment gives them a good opportunity to attain to a sturdy habit, provided the sowing has been carried out so as not to cause an overcrowded condition.

The importance of having the seedlings as strong as possible at the time when ready for pricking out is apparent when handling the small plants. The stronger are better furnished with roots, and the stems do not bend from weakness. The seedlings must be pricked out in rich soil on a spent hotbed, or in a frame with a layer of manure and a few inches of soil. Another method is to fill boxes 4 inches deep with good soil on a base of decayed manure as drainage. Place the seedlings about 4 inches apart. Stand the boxes in a frame close to the glass, keeping the lights closed for a time until fresh growth is made. The same treatment must also be accorded the plants pricked out in a frame or hotbed. Heavy waterings will not be needed, but slight sprinklings with a syringe or fine rose in the afternoon are of the utmost benefit. Afford air gradually in increasing quantity as the plants advance in size. During mild warm weather the lights may be drawn off, and fully expose for some time in May to harden for final planting early in June.

The trenches in which Celery is to be planted may be of a width to hold either a double or a single row of plants. For a double row cut the trenches 15 inches wide, and for a single row 12 inches. A good spit in depth is all that is required. Cut out the trenches straight, and place the soil removed smoothly on each side. In each trench place 6 inches depth of good decomposed manure, and mix well with the loose soil in the trench. This may be done a few weeks before planting, so that there is no delay when the plants are ready for transferring.

Dull weather just before rain is the best time to plant, and the soil in which the plants are growing should be moist in condition. The plants from boxes will lift out with balls of roots permeating the manure, and their removal causes little or no check. From the frames, too, the plants may be readily removed, but it is not desirable that they should be pricked out on a deep bed of manure, or the plants, if left too long, will become rank.

Water after planting to settle the soil about the roots, and should dry weather continue free supplies must be afforded until rain comes. Remove weeds from the trench, and sucker-like growths from the base of the plants as these appear. Abundance of water will be required as the plants grow. The soil may be loosened occasionally, and after the first trimming away of suckers chop down the soil on each side the trench, levelling it round the plants. This is preliminary to earthing, which should not be commenced before growth has brought the plants to a good size. Several earthings are better than placing the soil round all at once. The soil must be kept out of the

hearts of the plants either by a tie of matting round the leaves, or holding them closely together with the hand. Two persons can do this better than one. The final earthing may be carried out to within 8 inches of the tops of the plants, completing it about six weeks before wanted for use.—E. D. SMITH.

NOTES ON RASPBERRIES.

THE time has arrived when the final touches must be put on the Raspberry plantation, if they are not already accomplished. The work connected with the winter treatment varies in accordance with that bestowed upon the plants in the previous summer and autumn. If their sucker growths were reduced to a quantity sufficient for supplying the requisite number of canes for fruit-bearing this year, and the old bearing wood cut out in the autumn, then only the shortening of the fruiting canes remains to be done, so far as pruning is concerned. There is no gain, however, in crowding, so that if there is any tendency in that direction it may be rectified as the course of tying proceeds. Some still use stakes for supports, but the advantages of wire trellises are so many, that where it is practicable I would advise their early adoption. Two strands of wire will do, but three make neater rows.

The winter, so far, has been very favourable for Raspberries; in severe ones much damage occurs to the unripened tips and the buds, many of which fail to start. This happens, perhaps, more on heavy soil than that of a lighter character, and particularly where the ground is not sufficiently drained. Under no circumstances is it advisable to shorten back the canes until February is well advanced; pruning encourages water to gather in the pith, which, if frosts follow, causes much damage. When tying and pruning proceed together, it is easy to adapt one to the other. In some seasons it has been observed that unshortened canes brought to perfection the best crop. This points to the fact that the growth must be well ripened throughout, and this condition certainly ought to be in evidence after such a tropical summer as the past one proved to be. I have seen some gardeners bending down the points of the canes and tying them thickly to the top wire of the trellis, but whether an extension of crop justified the practice, I could not determine; certainly appearance did not.

Raspberries being surface rooting, deep digging among them is fatal to their well doing, especially if the following summer should be a dry one. If seedling weeds are numerous in the autumn through adverse weather, they may be skimmed off with the spade sufficiently deep to lightly bury them, and with a fairly heavy dressing of manure put on early become in time entirely suffocated, and instead of being an eyesore are by digging converted into plant food. Early attention to the Raspberry quarter allows of fresh strawy manure being used to advantage. Its soluble properties are carried downwards by the winter's rain, the slow decay of the insoluble matter provides food for roots in summer, and the straw makes the work of pruning and training easy and cleanly to the feet, advantages that cannot be other than beneficial to those who have the work to do, and the prospective crop as well.

The wet winter has very much hindered the work of planting, but the plants being early in their growth and root, there would be yet time to put this into practice in extreme cases. I should not in the least hesitate to remove plants at home, or purchase from a local nursery, but from a distance it would be perhaps better to defer planting until the autumn. The advice has been oft repeated, but the mistake is still made of leaving newly planted canes unshortened or only lightly pruned. No greater error can be imagined in Raspberry growing. The better practice is for all newly planted canes to be shortened to within a foot of the soil, which will be the means of providing a strong growth that will fruit next year. Mulching of new plantations is decidedly advantageous, and if it is possible, give water when the weather is continuously dry and summerlike.

Unless a high state of cultivation is practised, or the ground proves well suited to the Raspberry, it shows signs of debility after a few years, and the crop so depreciates that despair rather than pleasure becomes the ruling passion. In most gardens, however, it is a crop for which there is a demand that is seldom fully met, so that its removal from one site to another must be carried on piecemeal. Beds infested with bindweed or couch grass can only be cleaned by drastic measures, the best of which is by planting on fresh and clean ground.

Of varieties there are many, but the best of all, according to my experience, is Superlative, and those who do not number this among their collection, however small it may be, lose a good deal of pleasure as well as profit. Baumforth's Seedling is my next favourite; both give berries of large size, the first named in particular, and it is also distinct in every other respect.—W. STRUGNELL.

KEW IN EARLY SPRING.

As would naturally be supposed in a garden which possesses such large and varied collections of plants as Kew, a walk through at any time of the year is interesting and instructive; but to the ardent lover of plants probably no period has more charms than the early spring. After the dull days of the last three months, when hardy plants have been dressed in winter garb, it is particularly pleasing to note each flower as it appears, each tree or shrub as its buds begin to expand, or the delicate colouring of each young leaf.

In the arboretum during this time many beautiful sights are to be seen. Standing out conspicuously in exposed places are numerous groups of coloured stemmed shrubs, which on fine bright days are particularly attractive. Some of the handsomest are the red and yellow stemmed Willows about the lake, the red stems of *Cornus sanguinea* and *stolonifera* in other places; the bright brown stems of *Philadelphus* and *Neillias*, or the white stems of some of the *Rubus*, *R. biflorus* being the most conspicuous. In addition to these, a number of shrubs are to be found in flower as early as the end of January, while towards the end of February a considerable number may be seen. Of these some of the chief ones are *Erica carnea* and the variety *alba*, *E. hybrida*, *Daphne Mezereum*, *Hamamelis*, *Rhododendron dauricum* and *Nobleanum*, *Prunus Davidiana*, an early flowering form of the Almond, *Lonicera fragrantissima* and *Standishi*, *Chimonanthus fragrans*, *Spiræa Thunbergi*, and in sheltered nooks and corners quantities of *Rhododendron præcox*. The Bamboo garden shows how useful these plants are if planted in sheltered positions, their graceful arching stems covered with bright green leaves, making a charming picture among the surrounding deciduous trees.

In March the number of flowering trees and shrubs shows a considerable increase. Some of the most noticeable are *Pieris japonica*, with its beautiful arching racemes of white flowers; and *P. floribunda*, with its shorter erect racemes; the *Forsythias*, with their wealth of yellow blossoms; *Prunus divaricata*, *cerasifera*, *pendula*, *amygdalina*, and numerous others; *Ribes sanguineum*, *aureum*, and others; *Corylopsis spicata*, *Erica med terranea*, *Dirca palustris*, and a host of other plants. During this month, if the weather is fine, choice *Rhododendrons* may be seen in flower in the *Rhododendron* valley, some of the most striking being *R. fulgens* with its blood-red flowers; *R. Luscombei*, and several good garden hybrids.

The rock garden is always a source of interest. At each turn some fresh feature is seen, every stone shelters some choice plant, and each day shows an addition to the number of plants already in flower. On February 22nd thirty-six species and varieties were noted in flower, some of which were *Galanthus Elvesi*, *Ikariæ*, *nivalis* and others, *Saxifraga ligulata*, *Daphne Blagayana*, *Arabis albida*, *Narcissus minor* var. *minimus*, numerous *Hellebores*, *Iris reticulata*, and the common *Primrose*. The collection of *Crocuses* is very pretty, at present a large number being in full flower. In the herbaceous ground the small house devoted to Alpine plants is an attractive feature in spring. A select collection of the most ornamental things are grown in pots, and put into this house as they flower, a display of the very choicest Alpine plants being kept up for several months.

During recent years much has been done in the way of naturalising bulbs and other plants about the grounds at Kew, and by this means some charming pictures are made. Near the Palm house a mound is devoted entirely to wild gardening. In the arboretum another piece of ground is given up to the same purpose, while in other places large patches have been planted with bulbs and other things, all of which go to form a charming picture during spring. On the mound near the Palm house large patches of *Snowdrops*, *Crocuses*, *Daffodils*, and *Scillas* may be seen following each other in quick succession. In other places near by grassy mounds are thickly dotted with *Crocuses*; while a collection of hardy *Ferns*, among which *Primroses* and *Snowdrops* have been planted, look charming, the contrast between the old brown *Fern* fronds and the flowers being fine. In the arboretum large tracts under trees and shrubs are planted with *Snowdrops* and *Chionodoxas*, which are now sheets of white and blue. Later on large patches of *Daffodils* and *Bluebells* will be seen. One of the most charming features is the *Rhododendron dell*, the sides of which are planted with *Daffodils* between the *Rhododendrons*, the dark green and yellow contrasting admirably. For lovers of spring bedding a great display of *Tulips*, *Hyacinths*, and *Narcissi* is made in the beds near the Palm house and broad walk.

Indoors, to the majority of visitors the greenhouse No. 4 has certainly the greatest attractions. In this structure a fine display of the best flowering plants is always to be seen. At the present time some of the most striking are *Cyclamen*, *Hippeastrums*, *Primula stellata*, *Peristrophe speciosa*, *Cineraria kewense*, and *Camellias*; forced plants such as *Pyrus floribunda*, *Viburnum Tinus*, *Rhododendron sinense*, *Staphylea colchica*, bulbs of various sorts, and many other things. In the T range *Begonias*, *Acanthads*, and *Orchids* make a nice display. In the Palm house *Brownias* are the most striking of

the flowering plants, while in the temperate house *Himalayan Rhododendrons*, large *Acacias*, and *Camellias* are responsible for a fine show. In addition to the plants mentioned many scores of others could be added if space would permit. Those enumerated, however, will give some idea, if a poor one, of the number of interesting plants to be seen in flower any time during the next few weeks.—W. DALLIMORE.

APPLE SANSPAREIL.

New Apples of more than average merit are not very plentiful, consequently when one does come its exhibitor may count upon some considerable congratulation. Amongst the foremost of dessert Apples in the future must be placed *Sanspareil*, which was staged by Messrs. G. Bunyard & Co., Maidstone, at the Drill Hall on the 14th ult., when it received from the Fruit Committee a first-class certificate. In shape it is conical, broad at the base, and narrowing towards the crown; it is obtusely ribbed. It is rather above medium size, being 2½ inches in height, by 3 inches in width. The half open or closed eye is deeply set in a furrowed basin, and has erect blunt segments.

FIG. 52.—APPLE SANSPAREIL.

The thin stalk is deeply inserted in an even cavity, which is rayed with light brown russet. The colour is lemon-yellow with flushes of crimson, and splashes of brighter crimson on the side next the sun; it is strewn all over, but mostly on the shaded side, with brown pinhead spots. The cream-tinted flesh is tender, sugary, and of pleasant flavour. It is difficult to speak with confidence as to the keeping properties of Apples from Mr. Bunyard, as with this particular variety were staged several autumn Apples in perfect condition. *Sanspareil* is of continental origin.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE.—Present: Dr. Müller (in the chair); Rev. W. Wilks, Mr. Michael, Mr. A. Sutton, Mr. E. F. in Thurm, Rev. G. Henslow, Hon. Sec.

Celery, &c., attacked by grubs.—This was sent by Mrs. Barnet, of Bilton Hall, Rugby, and proved to be much infested by millepores (vegetable eaters) and centipedes (insectivorous), but not wireworm. The best remedy for these troublesome grubs is gas lime, or ordinary slaked lime (builders' second quality), well mixed and dug in. It may possibly injure the next year's crop to some extent.

Sweet Pea seed.—Mr. Sutton described specimens of the seed of certain varieties grown at Reading, remarkable for the skins becoming wrinkled like a Marrowfat Pea; while in one or two cases the Peas were so small that customers had thought they must be defective; whereas the smallest sorts really gave rise to plants bearing the largest and best type of flowers. In another variety the skin is invariably split. With none of these peculiarities, however, is there the slightest deterioration in the quality or character of the blossoms.

Shirley Poppy seed.—Mr. Wilks observed that the seeds of these Poppies are becoming of a pale grey colour, instead of being nearly black, as was originally the case with the old type of the cultivated *Papaver Rhæas* bearing black anthers.

Apple graft variation.—Mr. Wilks showed samples of the Mannington's Pearmain Apple sent by Mr. Peter Veitch, and taken from the original tree which supplied the fruit described by Dr. Hogg fifty years ago. It

is a medium sized Apple, russet in appearance, and rugose with raised lines, though the sample has scarcely a trace of bright colouration, as stated in Hogg's description. The "improved" form was devoid of all roughness, and brightly coloured with yellow and red. It is now widely distributed by grafting, and this improved form is the present recognised "Mannington," though widely different from the original type. Professor Bailey records an analogous case in America, in that since the original Newtown Pippin has been distributed over the United States, it has assumed various forms, specially characteristic of Apples growing in the different States, and even in Australia it has also acquired the local character of Apple.

THE YOUNG GARDENERS' DOMAIN.

A HOMILY.

It may be considered a happy thought that induced the *Journal* to afford a portion of its columns as a domain for young gardeners who felt inclined to profitably devote a portion of their spare hours to writing on gardening subjects. Really efficient horticultural writers are none too plentiful, and if the *Journal of Horticulture* is to fulfil its functions, and maintain and advance beyond its present level, it is necessary that young recruits should be induced to join the ranks.

In joining the colours young aspirants of the present ought to be considered better fitted to take the field than were those who are now putting off their armour. A sound elementary education has in their case been much more easily attained than it was when their forbears were young; and there is certainly a more numerous crop of subjects about which to write and discuss, and far more facilities for putting their writings into print.

Committing thoughts and observations to writing is to be strongly recommended for various reasons. It never fails to have a stimulating effect upon the mind of all who essay the attempt; it makes them more careful observers in the field of their daily labours. Observation or taking notice is one of the chief factors in evolving an accomplished cultivator. Writing of the value of this faculty, I think it was Dr. Johnson who said that some men learned more in the tour of Hampstead Heath than others learned in the tour of Europe. What a field of fertility in this respect does a modern garden establishment in its varied details afford. In few things does the proverb of "learn young learn fair" become more fully realised than in the early culture of the habits of carefully noticing, and in committing observations to writing.

Aspirants to horticultural honours would do well to be impressed with this fact. It is well known how strong is the general and natural tendency of youth to be so much absorbed in what may be termed the frivolities of life, as to lead him to perform his most interesting daily work without much serious thought, not questioning the whys and wherefores of what he is engaged in, or questioning the unerring natural laws of the marvellous organisms and their functions with which he is dealing and tending. His day of reckoning is, however, sure to come when it is too late to repair the negligence. But it is not my intention at present to pursue this phase of my subject any further, the able manner in which another "Old Boy" has dealt with such matters rendering it unnecessary.

Having been instrumental in my time of activity in inducing young men (some of whom have in no mean way graced these pages) to join the ranks of horticultural writers, I have taken an interest in the "Young Gardeners' Domain," and have followed it pretty closely. It may be said that some of the youthful writers give promise of good work for the literature of horticulture as well as in arduous work of the garden. I have, however, noticed with something like regret that they have almost entirely ignored the vegetable and hardy fruit departments, or at all events not taken so much notice of them as they deserve. Their subjects have, I think, been too exclusively taken from the glass department, no doubt one of great importance, and I do not profess to say that any section is much more important than another.

The kitchen department cannot be considered of little importance, or will it be thus regarded by those who, like myself, have been responsible for half a century for the satisfaction of those immaculately clad individuals who are at the head of the cooking department. It may be said without exaggeration that most gardeners have found the kitchen to be the quarter from which the most constant and exacting demands come all the year round.

I know from long experience that young men, entering their professional career, treat the cultivation of vegetables with far less consideration than they should do. They are constantly aspiring to the glass department long before they have become conversant with that for vegetables, or felt the importance of how to crop a kitchen garden in the most profitable way and so as to keep a supply in due proportion all the year round. With few exceptions it has been my rule to place all young

men who came under me first in the kitchen garden, and as a rule I found those who acquitted themselves well there turned out creditably in all departments. I never yet found a youth who was a good spademan who was not a good all-round workman, and a good workman generally turns out a good cultivator. If I were called upon to test a man by one operation I would hand him a spade and set him to dig, as I never found a good spademan in whom there was not a satisfactory general outcome.

I would urge upon those young men who aspire to enrich the "Young Gardeners' Domain" not to treat lightly with their pens the department for which I am pleading, and the importance of which they will sooner or later recognise. They may rest assured that it is a most important one, in which there is much to learn and interest. Its high-class management calls for much thought and forethought. There are these very few points among many:—The selection of the finest and most profitable sorts of vegetables; their sowing and planting times so as to maintain a constant supply in good condition; the rotation of crops; the best methods of culture; and the correct knowledge of the quantities of seeds necessary to crop a given acreage of ground for constant supply.—D. THOMSON.

VINE CULTURE.

It has long been my contention that it is not possible to lay down hard and fast lines on many points connected with Grape culture which would be universally applicable. Positions, structures, climate, and, in particular, soils, differ surprisingly, so that a method of treatment which answers well in one district might prove a failure in another. The object I have in view is to give a system of procedure such as by practical experience and careful observation I have found productive of successful results.

Before starting Vines into growth both structures and occupants must undergo a thorough cleansing. The borders may then be examined, and all surface soil removed down to where the roots are abundant. Replace this with a compost of four parts of good fibrous loam to one of mortar rubbish; charcoal, wood ashes, half-inch bones, and lime should be incorporated with the compost for top-dressing. It must then be made moderately firm and the borders adequately watered. I have often heard that if Vine borders are well drained they cannot be overwatered during the growing season. In my opinion, however, such an assertion is an error and often leads to unsatisfactory results. I believe many Vines are ruined by excessive watering, as some soils have a greater capacity for holding moisture than others. When admitting air to vineries one cannot be too careful, as a cold draught during the early stage of growth will practically ruin the future crop. We have to be guided in a great measure by the weather, and one important item is to change our ventilator just as often as the weather changes.

When starting Vines into growth no artificial heat will be required for three weeks, but the Vines must be syringed and the houses kept close. As the growth advances gradually raise the temperature to 50° or 55° at night, with 5° to 10° more during the day with air. Close early as the sun leaves the houses, but admit a little air during the night, as this will insure a sturdy growth and maintain a healthy atmosphere in the house.

In disbudding remove the weakest growths, leaving not more than two at each spur, and should these be close together leave the one showing the better bunch. When the shoots get near the glass carefully draw down to the wires. I do not consider it advisable to have either wood or foliage particularly large, but it is essential that both be healthy, of good colour and substance. Each leaf must be allowed sufficient space to develop without crushing its neighbour.

As the flowering season approaches gradually raise the temperature from 5° to 10°. Remove all surplus bunches, and admit as much air as possible without causing a draught; dispense with syringing altogether, and keep the atmosphere somewhat drier. Give the Vines a gentle shake a few times during the day to disperse pollen.—J. F. D., *Yorks.*

(To be continued.)

EARLY PEACHES AND NECTARINES.

PREVIOUS to starting a house, all necessary operations should be done after the foliage has fallen from the trees, such as washing the glass and woodwork, pruning, scaling, painting the trees with Gishurst compound, tying and top dressing the border if required. In tying always keep the fruiting wood on the top as much as possible, so that it may get the full benefit of the sun. If the borders require top-dressing, remove the surface soil down to the roots, taking great care not to break any; and if dry, give a watering, after which apply a mixture of good maiden loam and old mortar rubble, using four parts of the former to one of the latter; do not add it too heavily, and make it fairly firm by beating with a fork.

If fruits are required to be ripe by the middle of April and the beginning of May, start the house at the middle of December, affording a temperature of 40° to 45° at night, 45° to 50° by day artificially, allowing a rise of 5° from sun heat. Syringe the trees lightly with tepid water on bright days in the morning when the thermometer has reached 55°, also at midday, but in dull weather damping the paths and border will be sufficient. In about a fortnight from the time the house was started, raise the temperature 5° both for night and day. Great care must be taken in ventilating; do not admit any air until the house has a temperature of 55°, closing again at midday, allowing a rise of 10° from sun heat. Examine the borders occasionally to see if they require water; if so, apply it forthwith, for if permitted to become dry it will cause the

buds to fall; but on no account overdo it and make the borders sodden. Protect the outside border from frosts, snow and rains, covering it with straw or leaves, not too thickly, otherwise it will ferment, which will do the trees injury; place wooden shutters or strips of galvanised iron on the top of it.

When the buds are swelling raise the temperature again 5° both night and day, and if any aphids are perceived fumigate with XL. All vaporiser. Discontinue syringing when the buds are showing colour, but damp the border and paths two or three times on bright days. When the flowers expand brush them over at midday with a rabbit's tail fastened to a stick, to distribute the pollen, so as to insure a good crop, and when doing so keep up a free circulation of air in the house. After the fruits are set and beginning to swell, the trees should be syringed again, morning and at midday, charging the evaporating troughs with weak liquid cow manure, and raise the heat to 55° to 60° at night, 60° to 65° by day. Attend to the disbudding and thinning, removing a little at a time and often, because removing in great quantities will arrest root action and cause a check to the trees. At this stage when watering sprinkle some artificial manure on the borders, so that it may be washed in, and use soft water, as this will benefit the trees during the swelling of the fruit. Lay in the growths which are intended to fruit the following season, tying them very loosely, and remove laterals. Do not force the fruits too much when stoning, for if subjected to a high temperature it will cause them to drop. When stoning is completed the temperature may be again increased. Use the syringe frequently to keep red spider, thrips, and black fly at bay.

As the fruits begin to show colour, turn them up to the glass to get the full benefit of the sun, and remove all foliage from them, keeping in that position by placing them on labels or pieces of lath tied to the trellis, and afford a temperature of 65° to 70° at night, 70° to 75° by day. With signs of ripening discontinue syringing, but well damp the paths and border on sunny days, and afford a little air at night to improve the flavour. Look over them twice daily and gather those that are fit, and if not required to be used forthwith, they will keep for some considerable time if stored in a fruit room. After the fruits are gathered, the trees should be pruned, leaving the growths that are to fruit the following season about 3 inches apart, and on the top side of the branch if possible. Again syringe the trees two or three times daily, taking care to wet every part thoroughly each time it is done, and give plenty of air on all favourable occasions. Do not let the borders lack moisture, and when watering, it will be found beneficial to the trees if a little lime is sprinkled on and washed in.

The following varieties are suitable for early use: Alexander, Waterloo, Early Beatrice, Hale's Early, and Royal George Peaches, with Cardinal, Early Rivers, Lord Napier, and Violette Hâtive Nectarines.—P. R.

FRUIT FORCING.

Melons.—The earliest plants in houses are now well advanced, and if stopped when they have extended about two-thirds across the trellis laterals follow, with fruit showing at the second or third joint. To insure a good and prompt set of fruit afford a bottom heat of 80° to 85° , and sufficient water only at the roots to prevent flagging. This will arrest growth, and in combination with a rather dry atmosphere, a circulation of warm air passing through the house will favour the production of pollen. When this is ripe, fertilise the pistillate blossoms as they expand every day, and stop the shoots at the same time one joint beyond them. When the fruits commence swelling earth-up the roots by placing warm soil against the sides of the ridges or hillocks. Apply water as required, but avoid a soddened condition of the soil, duly maintaining moisture by sprinkling the paths in the morning and evening, and syringing lightly at closing time in bright weather. If a succession of fruit is required in the same house, deprive some of the plants of the flowers that appear on the first laterals. Stopping those at the first joint will cause the sub-laterals to show fruit, which will be later and finer, owing to the increased vigour of the plants.

Vines.—*Fruiting Vines in Pots.*—Those started early in last November will now have the fruit stoned and taking the last swelling. Surface-dress the pots with rich material and feed with liquid manure. When the Grapes are evenly coloured supply pure water only, and just enough to preserve the foliage fresh and the fruit plump.

Early Houses.—The Vines have, as a rule, made satisfactory progress, but there are cases in which the Vines have started slowly and broken irregularly, a few bunches showing a tendency to blindness, and others twisting and twining in any but the right direction. In such instances a slight increase of temperature and a reduced supply of moisture for a short time may be beneficial. Thinning the berries should be kept well in hand, commencing as soon as those likely to swell freely can be detected, and as a rule thin well in the interior of the bunches, leaving the berries with room to attain their full size without wedging, and yet so full as not to fall out of shape when placed on a dish. Liquid manure applied to inside borders will materially assist the swelling of the Grapes

after thinning, but it is best to vary the diet, giving a top-dressing of some approved fertiliser about every three weeks.

A liberal supply of atmospheric moisture is also necessary, and, if moderately charged with ammonia, it is beneficial to the Vines and inimical to red spider. It may be secured by sprinkling the border and paths with guano water, 1 lb. to twenty gallons of water occasionally, or better still, supply a mulch of sweetened horse droppings a little at a time over the whole border, but too much at once will prejudicially affect the foliage. Sharp winds necessitate care in ventilating, so as to avoid sudden changes of temperature and moisture, and thus crippled foliage and rusted Grapes may be avoided. Air should be admitted with great care in such weather, closing early in the afternoon at 85° , allowing an advance of 5° , and from that point the temperature should gradually fall to 65° at night. During the daytime the heat should be maintained at 70° to 75° when the sky is overcast.

Grapes that have passed the stoning process ought to have copious supplies of liquid manure in a tepid state. Avoid the close stopping system until the trellis is evenly covered with foliage, as every leaf promotes root action and assimilates food, which it is necessary respectively to maintain active and as clean as possible for securing properly swelled berries, but remember that this also depends on the full exposure of every leaf to the light, therefore avoid the least tendency to overcrowding.

Succession Houses.—Disbud and secure the growths as they advance, stopping them two joints beyond the bunch where the space is limited, but where there is room allow a greater extension before stopping. Remove the laterals from the joints below the show of fruit, except from the two basal leaves, which may be stopped at the first leaf, and to one afterwards as produced. The laterals above the fruit may be allowed to make such growths as can have exposure to light without crowding, and then be stopped, keeping them closely pinched afterwards, as well as in the case of those having room for extension. Remove all superfluous and ill-formed bunches of the free setting varieties as soon as those most promising for the crop can be determined.

Vines started at the beginning of the year will be in flower. A rather dry atmosphere, with a free circulation of air, and a temperature of 65° to 70° at night, and 70° to 75° by day, are conducive to a good set, moderate moisture being maintained by damping the house two or three times a day in bright weather. Any shy setting varieties, such as Muscats, should be kept 5° higher, the flowers being carefully fertilised, taking pollen for the purpose from those varieties that afford it plentifully, such as Black Hamburgh, Foster's Seedling, and others.

Late Houses.—Start the Vines intended to afford fruit from August onwards—indeed, Muscats, Alicante, Lady Downe's, and other late sorts should be encouraged now, as the fruit keeps much better when ripened early in September than when the season is more advanced at the ripening period. Gros Colman and Gros Guillaume require a long period of growth, hence start them without delay. Inside borders should be brought into a thoroughly moist condition, but avoid needless watering, as it only tends to retard root action, and in many cases causes the smaller fibres to decay, and shanking is the consequence. The outside borders are not benefited by protective material after this, but care should be taken to keep the stems of any Vines that are planted outside well wrapped in hay-bands. The atmosphere will be kept sufficiently moist by damping floors and walls two or three times a day— 50° is a proper night temperature, and 65° by day with sun. Depress any young canes to the horizontal line or lower, so as to insure their starting the buds evenly throughout their entire length. In the case of late Black Hamburghs the Vines may be kept cool, and they will then start naturally next month.

THE KITCHEN GARDEN.

Jerusalem Artichokes.—The weight and quality of crop is greatly improved when this vegetable gets fair play. Instead of being allowed to come up thickly on the same site year after year, fresh plantations should be made each season. A deep, well manured freely worked soil best suits this crop. Open drills about 6 inches deep and 3 feet apart. In these plant either medium sized whole sets with the first strong shoot intact, or cut large tubers into two or three sets, each with two or three shoots or eyes, disposing them 1 foot apart. In all other respects treat similarly to Potatoes. The old plantation should be dug over, every tuber found thrown out, and all worth saving for use during the next week be cleared of sprouts and stored in sand or soil till wanted.

Early Carrots.—Only the smaller early varieties of Carrots should be sown as yet: early sowing of the intermediate and longer rooted sorts resulting in the production of coarse, deformed roots, unfit for storing. A small portion of a warm border or slope may well be devoted to early Carrots, and this should be got into as finely divided a condition as possible, adding to the heavier soils a dressing of sand or sandy soil, forking, not digging, this in and mixing it with the surface soil. Draw shallow drills 9 inches apart, sow the seeds regularly and not too thickly and cover with fine soil.

Chicory.—Large Carrot-like roots produce the finest tufts of leaves when forced, and in order to procure these a fairly long period of growth must be allowed. If the ground was well manured for a preceding crop of any kind, all the farther preparation is deep digging, followed by making the soil fine to a good depth. Shallow drills should be drawn 1 foot apart, the seeds sown thinly and covered with fine soil. The seeds being small and cheap are frequently sown thickly, with the result that nearly or quite all grows, and much thinning out is needed accordingly.

Onions.—Directly the ground can be got into a suitable condition, the seeds ought to be sown. If the ground has been previously heavily manured, dug deeply, and, if of a heavy nature, laid up roughly, it may be

found an easy matter to break it into small particles. Should it be hard and tough, March winds and sun, followed by rain or an application of water, ought to cause it to crumble readily, and better wait for this than to bury seeds in rough lumpy soil. Firmness, as well as a rich root run, is necessary for Onions. The poorer, lighter soils could be greatly improved by a surfacing of soot, 1 peck to the square rod, common or manure salt 2 lbs. to the square rod, and a liberal dressing of sharp road grit, stirring this into the surface. Trample the ground heavily, make all fine and level, and draw shallow drills 10 to 12 inches apart. Sow the seeds thinly, make firm, and finish by raking across the bed. Autumn sown Onions may be transplanted now or a little later, and if the work is done in mild or showery weather, the plants will experience very little check in transplanting.

Parsnips.—Parsnip seeds are usually sown in February or as early in March as the ground can be got into a suitable condition. This plan may be followed with advantage by those who require extra large roots, but medium-sized to small roots are the best from a cook's point of view, and later in March, or even early in April is, as a rule, a better time to sow. Parsnips ought to have a deeply cultivated soil, and if any manure is used this must be buried deeply, as should the tap roots come into contact with solid manure they are liable to fork badly. Sow the seeds thinly in shallow drills drawn 12 inches to 15 inches apart.

Salsafy and Scorzonera.—Much that was advanced concerning Parsnips also applies to these. Early sowing is also apt to result in many of the plants running to seed prematurely, and the roots are worthless accordingly.

Potatoes.—Advantage should be taken of a dry time for making a start with Potato planting. If, however, the ground is wet underneath, wait till it is drier and can be moved readily, the best crops resulting on soil that has been freely and deeply cultivated. Only the latest sorts should be planted on a large scale at this early date, but a few rows of early varieties may be planted in a warm position, or where a close look-out can be kept, and all the haulm that pushes through be protected when necessary. Sprouted sets are the quickest to grow and produce crops, and in planting care should be taken not to break these sprouts. Seeing that short-topped early maturing varieties are not long on the ground, they may be planted somewhat thickly, or say in lines 20 inches apart, and the sets 9 inches asunder in the drills.

THE BEE-KEEPER.

REDUCING ENTRANCES.

HIVES that have had their entrances open the full width throughout the winter may now have them reduced. There are several reasons why this should be done. In the first place robbing is often prevalent at this season. The strong stocks will attack a weak colony if the weather is warm. Abundance of stores in each of the hives has very little to do with the matter, as we have proved during the recent bright sunny days. The steps taken to prevent it may be interesting to others similarly situated.

On two or three successive days a great commotion was observed round the entrance of one of our hives which was doubled last summer, but owing to the prevalence of honeydew the honey was not removed from the top storey. The excluder zinc, however, had been removed, so that the queen and the bees had free access to all the combs. The entrances were all opened their full width last autumn, so there was no difference in that respect. On examination we found the rightful owners clustered in the top storey. We at once took steps to prevent the bees from the other hives gaining admittance. The entrance was reduced, allowing only sufficient space for one bee to pass through at one time, and turned from south to west. The sides of the hive and the alighting board were painted with a strong solution of carbolic acid. The steps taken had the desired effect, as when the bees from the other stocks attempted to gain an entrance they were stopped, and after a few hours' excitement gradually returned to their hives.

At first we were somewhat puzzled to know why the above stock should be attacked, as it was strong in bees, but have concluded that it was owing to the majority of the bees being in the top storey amidst ample stores, and they neglected to guard the entrance. The robbers were thus able to gain admittance, and would doubtless clear out the stores that remained in the combs in the body of the hive. The above shows it is an advantage to reduce all entrances to at least an inch at this season as a precaution against robbers; while it will maintain a higher temperature in the hive.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

•• All correspondence relating to editorial matters should, until further notice, be directed to "THE EDITOR," 8, Rose Hill Road, Wandsworth, S.W., and NOT to 12, Mitre Court Chambers, Fleet Street. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *nom de plumes* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Seakale after Forcing (Mack).—Seakale that has been taken up and forced in a Mushroom house or similar place will do to grow for stock, provided the plants are not very old, say not more than four years. We place the roots as the heads are cut in sand in an outhouse or shed, keep them cool until the beginning of April, and then plant in rows 18 inches apart, and place the plants about 1 foot asunder in the rows. As many growths issue from the crown of each set or plant, they should be reduced to two, or at most three, removing the smallest and leaving the most promising. They may again be forced the following winter, and so on.

Violet Leaves Disfigured (C. T.).—The leaves are infested by the Violet spot fungus, *Peronospora Viola*, which has been unusually prevalent this season. It chiefly arises from a humid atmosphere, and we can only suggest giving more air, and not having the plants very closely together, so that air can circulate freely about and through them. This, and removing the first spotted leaves, we have found the best preventive, also using dust charcoal freely about the plants. In bad cases it affects the flowering to such extent that they do not expand freely and fully—indeed, some never do more than form buds, the flowers being "blind," or nearly, if not quite, devoid of petals. The shrub appears to be the very handsome Californian Hemlock Spruce, *Tsuga Mertensiana*, syn. *Abies Albertiana*.

Eradicating Wild Garlic (J. M.).—In some woods, especially in hilly districts, this plant (*Allium ursinum*) grows abundantly, and often in patches of many acres, and is, as you say, very rank and disagreeable smelling, and "if eaten by cows the taint will be present in the milk." We may add in the butter, which it makes so bad tasted that we could never use it. Of course, cows ought not to be allowed in woods, but the fences of these kept in good repair. We have not found anything act so well as cutting the plants down with a scythe just before flowering. We used a short scythe, and where this was impracticable a scythe sickle, cutting as near the ground as possible. By repeating this every year the Broad-leaved Garlic gradually disappeared. Of course, rooting up is the better plan, but a serious affair in the case of large areas. Perhaps some of our readers may know of a readier means of extirpating this noxious smelling weed.

Non-Success with Mushrooms (C. P. S.).—The failure cannot be attributed to the beds being made on the cemented floor, for we have grown Mushrooms on such bases quite as well or better than on shelf beds. We prefer these for convenience, keeping the floor clear, as you say, but only to the extent of a pathway up the centre or at one side, using the bottom beneath the shelves for forcing Rhubarb and Seakale. Slate or stone shelves are the best, supported in brick walls or brick pillars with T galvanised iron bearers. The fronts may be of wood, the board a foot deep, and kept in place by uprights, if fitting on the inside and resting on the shelf. The shelves may be entirely of wood, forming boxes about a foot deep. There should not be less than 3 feet between, so as to allow for the formation and attending to them with ease, and the boards must be $1\frac{1}{2}$ to $1\frac{3}{4}$ thick to bear the weight without much sagging. An inch board will do for the sides. The "brick" may be all right as regards spawn, but it neither smelt of Mushrooms, nor could we find life in it. The spawn appears to have been dried out of that—the portion sent being very old. The bricks cannot be too fresh, and if it be good you will succeed as you have done before under proper management.

Definition of a Professional Gardener (Coventry).—Yes, "a gentleman's gardener is a professional gardener where there is no other gardener employed," and must rank as such for every purpose—duty or annual licence, and competing at horticultural shows. The term professional, however, has no more than a relative significance, for gardening is not a profession, but an occupation, and applies to any and every "one whose occupation is to make, tend, and dress a garden." Where but one person is so employed, he or she is called a *single-handed gardener*; if more than one, there arise the terms *head* and *under* gardeners. When a person works his own garden, he is an amateur gardener.

Eggs on Apple Twig (C. C. E.).—The reddish minute knobs appear to us nothing more than russety excrescences, possibly due to a minute fungus of which we find the perithecia-like bodies, but there does not appear any substance in them, or at least nothing that we can define as either vegetable or animal organisms. The few black eggs in the crevices are those of the Apple aphid or fly, *Aphis malus*. There may be other bodies, but we failed to discover them. Nothing of which we are aware will destroy the aphid eggs but hot water, though caustic soda and commercial potash have been used with good effect, the solution being sprayed on at a temperature of 130° to 140°. One ounce each to a gallon of water is a proper strength. The solution must be used whilst the trees are quite dormant.

Silk Cocoon Liquid Manure (W. R.).—We are not aware of the article being now in commerce, but there can be no question of its efficacy for destroying mildew, as the cocoons are boiled for unwinding the silk in a copper vessel heated by charcoal, and the water thus more or less impregnated with copper and containing the gummy matter of the cocoons imparts an adherent consistence to the liquid. Perhaps a letter addressed to the Manager of the Lister Silk Mills, Manningham, Bradford, Yorks, would result in your obtaining the necessary information. We, however, have no personal experience of the article, but the gentleman mentioned in the article on "Grape Vine Mildew" in the *Journal of Horticulture*, December 21st, 1876, is a guarantee of its safety and efficacy for destroying mildew on Roses.

Treatment of Vine for Introducing to House (C. C.).—The Vine should be pruned to one or two buds of last year's wood, selecting the best of the three shoots for this purpose, preferably the central one, and cutting the other two away close to the cane or stem. The wounds should be carefully dressed with patent knotting or styptic to prevent bleeding. We presume the Vine has been planted out in the position it is to occupy. If not, it would be advisable to do so as soon as the weather becomes mild, spreading out the roots carefully, and not planting much deeper than it has been before. It will, or ought, to break strongly from the two buds left, and when they are fairly in growth remove the least promising, and secure the other to a stake, pinching the laterals to one leaf, and you will secure a strong cane, which may be introduced into the house when long enough, and preferably as soon as convenient, so as to secure well ripened wood.

Manure for Narcissi and Daffodils (A. L.).—Of animal fertilisers the best for a light soil is cow manure well decayed, for a "sandy clay" farmyard, and for clay land horse droppings. The two latter also should be well decomposed, as fresh has a tendency to "flush" the bulbs into too much leaf. We do not know in what way Narcissi can be injured by the ammonia of horse manure, unless it were used fresh. We have used sweetened horse droppings as a mulch over Narcissi beds with satisfactory results, the whole family growing in places where they get a rich surfacing of vegetable mould, and thriving accordingly. Of course it is not fresh, but results from decaying vegetable matter; therefore use the manure well decayed. For *Lilium candidum* and *L. speciosum* (lancifolium) album, we have not found any better manure than that of cows for light soil, as it is cooler and more moisture holding than horse droppings, the two mixed for medium textured soil, and horse alone for heavy land.

Pruning Dwarf Hybrid Perpetual Roses (H.).—There are always different opinions about pruning Roses, simply because those having them have different objects in view. The gardener no doubt had that of fine blooms with stout stems for cutting purposes, and keeping the bushes dwarf, strong, and healthy as long as possible, hence his advice to prune the weak wood to two or three eyes and the strong to four or five. Our practice nearly approximates to this, but we cut away all the weak wood, as it never flowers or the blooms are poor. The healthy but weak shoots are cut back to a bud of their base, the medium or moderately strong to two or three buds, and the strong to four to six eyes. This is the practice we have followed for many years, and found satisfactory, our object being to secure good trusses of flowers for cutting and fine blooms for specimen glasses. The pruning is best deferred until the end of March or beginning of April, or even later, as the young growths at the extremities of the shoots attract the sap and induce root action without starting the basal buds, and thus kept back they start strongly when the bushes are pruned and the growths from them escape the late spring frosts. The other plan you mention has for its object the production of what are called garden Roses, or an abundance of flowers, and against it we offer no objection, provided the trees grow sufficiently vigorous each year to produce strong shoots and ripen them. By the long pruning system the old wood must be cut out when it becomes weak in order to secure strong growth. In some cases the shoots are left almost entire, only the unripe tips being cut off, and the shoots are sometimes pegged down.

Names of Plants (C. D., Kent).—*Allium neapolitanum* (T. H. B. and J. P.).—Not yet identified, see next issue. (L.).—Through having been packed in cotton wool the flower was quite dead and no one could possibly identify it. Send another properly packed, and we will do our best to assist you.

HORSES FOR PLEASURE AND PROFIT.

IN these days of darkness and depression (agriculturally speaking)—a darkness that may be felt—it is a serious question as to what industry will make any return to the farmer. So much is labour in vain, and worse than that, so much of enterprise spells "loss." Indeed, it may be accepted as a fact that no old-fashioned plans are of any avail, each farmer must have some speciality—something over and above his ordinary routine work. Only one string to the bow, or all eggs in one basket, will never answer, and the question must be decided by each individual as to what outside branch or "extra" the farm and the man are best fitted for.

Every man by birth and education has a bias; that bias must be turned to account. As a general rule, it will be found that Yorkshire men have kept in the same groove for generations, and that the groove is a good and profitable one has been fully proved by the success which has attended their efforts in that direction. We refer to the breeding of light horses. In old days, say the time of our grandfathers, it was a case of coach horses. Now hunters and harness horses generally have come to the fore.

Happily no substitute has been, or can be, found for a weight-carrying hunter, and he may safely breed carriage horses for some

time yet, despite the new invention. Remounts, too, are always in request for our soldiers, and should a war break out horses might soon reach famine prices. As long as England exists the sport of kings and commoners alike will demand good horses, and plenty of them. This open season particularly impresses an observer with the fact that a very brisk trade may be done by the fortunate possessor of a few sound horses. Here we are in February, only one week's rest all the season, horses fairly "dished" all round, such difficulty in getting a sound mount, and such racing and chasing if it is known anyone has a horse on sale; and the class of people who need them are both able and willing to give a long price.

"In all work there is profit," and if with the profit you can combine a little pleasure so much the better, and in the "making" of a hunter you get the chance of many a nice little day after hounds. In breeding hunters the first consideration is yourself. However pretty and good a thing is, if it will not meet a market it is of no use to you. Find out what is wanted, and breed to order. The majority of customers expect to have the eye filled, and to get plenty for their money, and so to cater for these "gents" you may safely dispense with much blood. Have some good earl mares, not big enough or fashionable enough to breed "Shires," mate them with a thoroughbred horse, sound all round, standing about 15'3, of proper action and substance. It is said a good horse cannot be a bad colour, but there always will exist a prejudice about colour, and so the sire should for choice be brown or bay with black legs. In all probability the fee will not exceed £2 2s. per mare—most owners, however, make material reduction in case of numbers.

The mares should be gently worked up to the day of foaling. Avoid potato leading in autumn, and manure filling in very soft weather, also see that the waggoners are not ruffians either in or out of the stable. After foaling keep the mares up for ten days or rather more. Then begin light work again. The foals are better left at home in boxes; they get a bit of corn, and are safer from accidents. When weaning time comes, submit each foal to a searching scrutiny, and at any price get rid of such as may show signs of bog spavin, ring bone, crooked legs, or curby hocks.

When three years old any colt that looks like harness can easily find a market (unbroken) at prices ranging from £40 to £80. The £80 ones will be even movers, of good colour, 15'3 to 16 hands high.

The question may be asked, Why sell them unbroken? In the first place no great buyer of carriage horses will ever look at a horse that has gone through any form of discipline except in the hands of his own breaker. A bad fault or two takes so much eradicating that the game is not worth the candle. Breaking is a heaven-born gift. Secondly, in breaking a young horse, a certain amount of risk must be run, and rather than spoil the whole thing for the sake of a few extra pounds, let someone else take the chance.

The less attractive colts and some of the fillies find a market as soldiers' mounts, or, maybe, go to horse some of the innumerable provision carts that over-run the country. Others find a sphere on the farm where a light horse is of the greatest service; he steps away and gets over the ground in a manner truly surprising, and is ready at a pinch to take master to market or missus to a tea party.

When rising 4, the pick of the bunch should be regularly ridden round the farm all the winter, and allowed to see hounds as often as practicable. Do not knock them about. Remember, now is the time when you are spending that extra 2d. per week for manners. No one likes an ill-mannered, fretful horse. Put them at small places, and never let them refuse. Let your watchword be, "Eternal patience." Be content with short days, and in keeping your own temper you make theirs. There are plenty of knowing men always on the out-look; they want them for show purposes, and, eventually, they get into the hands of rich buyers, who do not grudge to give £200 to £400. Personal recollection points to fifteen or twenty animals that have fulfilled these conditions out of cart mares by thoroughbred horses. We can remember one mare in the long ago, bred on these lines, who, with her foals, cleared every board, and that year after year.

These horses just suit the average hunting man—he thinks he is getting plenty of bone and muscle for his money—they are easy to ride, and not too keen. They never look so well as they do at four years old, and even if it is by accident a case of "bellows to mend," they are cheap in the shafts at from £40 to £60.

A man may be a good breeder of hunters but not a good man to hounds; therefore, in that case he cannot expect to make so much as a man who with a good seat and superb hands would almost sell a donkey. If he is known as a reliable man, he need never have a horse hang long, but he cannot expect to make the fancy prices that the latter man may, and can, command.

We do not argue for a moment that horses of this type are ideal hunters, but they are selling ones, and that is the great point we are looking at. The longer the pedigree the greater the risk. First-rate hunters must have at least six or seven distinct crosses, or be absolutely out and out thoroughbred. Mares of this class are bad to find, and almost beyond the purse of the ordinary farmer, and it will only be by very good luck that three brood mares will provide the owner with two saleable four-year-olds every season.

Blood horses, too, take much more training than the commoner ones, and are not at their best till six or seven years old. This means too long a wait before there are any returns, and few farmers can give so much credit.

WORK ON THE HOME FARM.

With March winds come dry seed beds, and given a properly pulverised soil, the sooner spring corn is in the better. In nine cases out of ten, or even nineteen out of twenty, it is the early sown seed that makes the heaviest bulk and the best sample. But let it be understood that when we say a "well prepared seed bed" we mean it. No sodden stiff land will do; a free fine mould, like a bit of real good garden, and this is generally attainable the second week in March.

Keep the land ploughed up close to the sheep; there is nothing like being "torrad" with work, and besides, the sheep manure does more good to the land by being well "happened" up.

If Wheats incline to be thick, nothing beats a good harrowing, that is if the state of the land allow of it being worked. Harrowing is like pruning Roses or thinning Grapes—it is hardly possible to overdo it. It is the natural habit of Wheat to branch, and a harrowing permits freer access of air and sunshine.

The lambing shepherd is much in evidence just now, and a good man finds his work no sinecure. There are always ewes whose supply of milk is deficient, and lambs soon succumb to cold, stormy weather unless they have a well filled stomach. A good cow is of infinite help to a shepherd, and he must be prepared to supplement with a sucking-bottle the maternal supply.

A generous diet for weakly ewes and ewes with pairs is advisable. In very rough weather all will be the better for a few extras, say a mixture of oats, cotton cake, and malt culms. We hear people talk of "luck" in lambing; well, the "luck," good or ill, is the result of judicious or injudicious management. We do not believe in "luck." We make our own.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

26th.—Almost cloudless throughout.
27th.—Sunny, but generally rather hazy, and fog at night.
28th.—Fog all morning, bright sun in afternoon, clear night.
1st.—Cloudy morning, sunny afternoon with halo, much milder.
2nd.—Bright sunshine throughout.
3rd.—Fog nearly all morning, bright afternoon.
4th.—Overcast till 10.15 A.M., then generally sunny morning, spots of rain at 1.15 P.M., and shower about 3.30 P.M., then sun again.
A cold, dry week, generally sunny, with clear frosty nights. Barometer very high on the 28th.—G. J. SYMONS.

A FEW SPECIALITIES.

Barr's Monstrous Long Pod Broad Bean.—The earliest, best flavoured, largest podded, and most productive. Per quart, 2/6.
Barr's Green Haricot Dwarf French Bean.—Of very delicate flavour, and unsurpassed as a Haricot Bean in Winter. Per quart, 2/6.
Barr's Best of All Autumn-cutting Cabbage.—Dwarf and compact, very early and of exceptionally fine cooking quality. Per packet, 6d.; per oz., 1/6.
Barr's Earliest French Short Horn Carrot.—A favourite for soups, and extremely early; the best variety to sow in frames. Per packet, 4d.; per oz., 10d.
Barr's "Pride of the Market" Cucumber.—A specially fine dark-green variety of handsome shape; a favourite in Covent Garden Market. Per packet, 1/6.
Barr's Long Keeper Onion.—A fine handsome Onion, and a very long keeper. Per packet, 6d.; per oz., 1/3.
Barr's "First of All" Radishes.—Scarlet or white, fine little, short-leaved, very early Radishes. Per oz., 6d.
Barr's Early Ruby Tomato.—Bright scarlet solid fruit of fine form; an abundant cropper; the best FIRST EARLY Tomato. Per packet, 1/-.
Barr's Thick-fleshed Tomato.—Surpasses all other varieties for depth of fruit, solidity of flesh, high quality, and heavy cropping. Per packet, 1/-.
BARR'S SEED GUIDE (Free) contains a full descriptive List of the best Vegetables and most beautiful Flowers, with many Practical Hints on Culture valuable to Gardeners, Amateurs, and Exhibitors.

BARR & SONS, 12 & 13, KING STREET, COVENT GARDEN, LONDON

THURSDAY, MARCH 16, 1899.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 8, Rose Hill Rd., Wandsworth, S.W.

PREPARATIONS FOR BEDDING.

THOUGH summer bedding in many establishments is not the business it used to be, still it is a matter of more than passing importance, and unhappy is the gardener who finds himself at planting time destitute of material to meet the requirements. Better, then, to take advantage of every facility afforded by the propagating house while there is yet time to raise and increase.

In spite of the many hard things said about the Zonal Pelargonium as a bedding plant it still holds a prominent position in many gardens, where it is the aim of the grower to have an adequate stock of dwarf compact plants ready for action at the end of May. For several months past the plants have been playing an inactive part, stationary in the boxes where they were rooted from cuttings; but young green tips and increasing growth tell plainly that the resting season is over. The growing of bedding plants perhaps belongs to the A B C of the gardener's work; but with this, as with other operations, if the small matters are neglected the result is invariably unsatisfactory. How often are bedding "Geraniums" left in the cutting boxes till late in the spring, and when shaken out and potted roots are mercilessly broken through being matted together, tops are elongated and crowded, and even if capable of doing it the plant has not time to recruit and assume a bushy appearance before it is drafted to the flower bed.

A glance at the bedding Pelargoniums now will show that no time should be lost in shaking them out of the propagating boxes, and transferring them to small pots. If the stock of any variety is low the tops may be pinched out, made into cuttings, and will root readily on a gentle hotbed. Spring propagation is necessary with some varieties of the tricolor section, such as Black Dogulas, which often do not make sufficient growth in the summer to get the full complement of cuttings, and consequently the plants have to be lifted and wintered, and a stock raised the following spring. There is little art, perhaps, in potting a bedding plant, and the work is generally entrusted to beginners. It is easy to make mistakes, however, in

this operation, and hundreds of plants may go off through putting them too deep in the pots, when moist soil pressing round the green stems causes decay. Having in view a dwarf bushy plant, the points of the shoots should be pinched out, to encourage a branching habit, and the plants be grown close to the glass in a cool structure till the time arrives for hardening.

So much for the Pelargoniums, and now a few reminders about the bedding Calceolarias. To many growers this plant is a source of constant trouble on account of its propensity to die off in the flower beds, thus leaving gaps which at that time are difficult to fill up. Many would dispense with it on this account, but we have no plant to take its place in making a display of bright yellow. The evil is often increased by two mistakes in treatment—viz., coddling and late planting. At no time does the bedding Calceolaria require more protection than that afforded by a cold frame, covered during periods of severe frost, and very often the fatality in the plants during the summer can be traced to late planting. It may not be the general rule, but still it is a common one, to leave the Calceolarias crowded together in the frame till other tender plants are put out at the end of May or early in June, and consequently they have no time to become strong and established before the height of the summer, when they invariably succumb.

April is the best time to transplant Calceolarias, and here a difficulty arises, for often the beds are tenanted by other plants at that time. I have overcome the obstacle by preparing a nursery bed of light soil and digging in leaf mould and sand. The plants are removed from the frames before they get overcrowded, and are planted in the nursery bed, from which they lift later with good balls attached. With this treatment I have had little trouble through plants dying off, though, of course, if the beds are at liberty early there is no need for the intermediate stage. Of the broad and narrow-leaved varieties the latter seems the more prone to the evil referred to.

There is abundance of work in the propagating house just now in preparation for summer planting. In the case of stored Dahlia tubers, Nature has asserted herself, and if left longer without attention, they will suffer. I have never experienced difficulty in raising good stocks of these indispensable plants from cuttings, and never followed but one method. The old tubers when taken from the store are placed on a bed on one side of a low span-roofed pit, in separate varieties, and on the other side light soil is spread several inches thick for the reception of the cuttings. As soon as growth commences, the cuttings are taken off and inserted in rows in the bed on the other side of the pit, taking care not to mix the varieties. The two rows of pipes running beneath provide a little bottom heat, and it is rarely that a cutting fails to root. When growth commences they are lifted with a small hand fork, placed in 5-inch pots, and stood in a cool house, where they remain till they can be placed outdoors with safety. Frequently young Dahlia plants are grown in pots so small that the growth becomes weak and stunted, and in consequence of this, the plants are some time before they get a good start after being removed to the beds or borders.

Blue and white Lobelias will always be popular bedding plants, and it is rarely that the stock of these plants is found to be too large. Many rely on seeds for their supply of plants, and if the strain can be depended on there may be nothing to say against this mode of propagation. Unfortunately, however, many plants raised in this way do not possess the dwarf, compact, free blooming habit which makes Lobelias so pleasing. Having got what you require, it is obviously a good policy to make an effort to keep it, and there is no better way of effecting this than to grow a few plants purposely for stock and propagating from cuttings. If inserted now in light soil in small boxes or pans, and placed over the pipes in a warm house, covering for a few days with a square of glass, Lobelia cuttings will root readily, and when large enough to handle they may be removed to small pots or be pricked off into larger boxes. Plants raised in this way are invariably more satisfactory than seedlings.

One thought suggests another, and much space could be readily filled in giving reminders about the important work of preparation for summer bedding. The fault of being too early in these operations may be remedied, but to be too late is often fatal.—H.

SPIRÆAS.

THE popularity of these beautiful flowering plants is still well maintained, although there are times when the most common variety—japonica—is placed upon the market in such quantities that very low prices are realised, and growers are inclined to declare that there is no money in Spiræa growing. I am inclined to agree with them to a certain extent; but only as far as this—viz., that they are unremunerative when placed upon the market at haphazard times. Let anyone produce a thoroughly good collection of plants in pots, and plenty of cut flowers at Easter and Whitsuntide, and they will find them fairly profitable.

In all private gardens, too, they are of great service at these festive seasons, for there is usually a large amount of decorative work to be done, for which nothing is more suitable than good plants of *S. japonica*—plants which have deep glossy green leaves, with the feathery plumes rising well above them. The newer varieties—*astilboides* and *compacta multiflora*—are good in their way, and are worth growing for the sake of variety; but to my mind neither of them is so generally useful as *japonica*, because almost before the flower spikes are fully developed a brown tinge may often be seen at the base of the flower spike, and the flowers never seem to retain their purity more than a couple of days after they are fully expanded.

The cultural treatment of the varieties above named may be considered identical, except that *japonica*, being the more plentiful, is usually relied on for early forcing. Spiræas are the simplest possible plants to grow when brought on gradually in a cool or intermediate house; but when subjected to sharp forcing a slight mistake will cause them to cut a sorry figure, the leaves becoming browned and curled almost beyond recognition. This state of affairs is brought about by several causes, but principally through overwatering. During the bright sunny days of spring, when Spiræas are growing rapidly, it is almost impossible to overwater them, and this fact leads many to water too freely early in the season. The great majority of cultivators who have at various times placed Spiræas in strong heat during January and February have, I suspect, found a few of their plants curl badly in the foliage, and may not, perhaps, have made any special attempt to find out the cause. I have frequently watched such plants closely, and have found that if they are turned out of their pots as soon as the brown tinge is noted in the edges of the leaves, the roots, though white in some parts, will be brown in others.

In cases where the roots are not examined till the plants are in a more advanced state of disfigurement the roots will be found quite brown throughout, and in many places decaying, the soil being quite wet. It is also a matter of some surprise to note how very few roots have been formed compared with the entangled masses to be found in the spring. The above remarks show how comparatively little water is required early in the season. A too dry state of the atmosphere also aggravates the evil, and although it is not wise to keep the foliage continually saturated with moisture, the floors and stages of the house ought to be uniformly moist.

During March and April, when the weather is bright, strong clumps will require immense quantities of water. They should be examined twice and often three times daily, always endeavouring to apply water just as the soil is beginning to get dry, then giving it copiously. When plants are placed on dry stone or slate stages saucers placed under the pots will greatly lessen the labour of watering, but should dull weather prevail for several consecutive days it is a good plan to empty the water in the saucers and fill them again when bright weather comes. A weak solution of soot water is, I think, the finest of all stimulants for Spiræas, though other kinds of liquid manures are beneficial when applied occasionally. Vineries in which Spiræas can be set upon the border are excellent positions to force the plants in, as the moisture arising from the damp soil suits them to perfection.

S. aurea reticulata is an excellent variety for forcing in both pots and borders in the open air, as the golden-striped foliage forms a fine contrast to the majority of other spring-flowering plants. *S. palmata* (scarlet), and its varieties *alba* and *elegans* (rose), are grand for pot work, as they throw their huge spikes to a great height, and these, combined with the large handsome foliage, supply striking plants for room decoration. The flowers, too, are always useful in a cut state on account of their long stems. It is not wise to attempt to force these varieties rapidly, for they are seen at their best when brought on gradually in quite a cool house, but when required earlier they will bear gentle forcing if a free circulation of air is kept up.

When grown in the open air they are usually planted in mixed borders, and in such positions they are so effective that it is a pity to have to cut the flowers for filling vases. By a little systematic management this, however, may be avoided, as the clumps grow rapidly, and may be quickly increased when liberally treated. The plan I recommend is to divide the plants into as many pieces as possible as long as each has one strong crown. Do this in the autumn, and plant them in well-manured soil in the reserve garden. Keep the

soil frequently stirred during the spring, and in summer mulch with short manure. With this treatment grand spikes of flower on sturdy stems are produced, such as the decorator often envies, but cannot always obtain.

The demand for ent flowers is now so great that practically the only way to produce large quantities in really good condition is to devote a certain amount of space to each kind.—H. D.

ORCHARD NOTES.

THE improvement in the fruit cultivation of the country is silently and steadily going on, and is the result of a variety of influences. There are, for instance, the more inquiring spirit of the age and the spread of the literature of gardening over a wider area than in any previous time, and at a price to suit the humblest pocket. To satisfy that craving for knowledge, too, there is the quiet influence of the best gardeners freely exerted in their respective neighbourhoods. Added to these we must put the clear, and therefore easily understood, directions as to planting and management contained in the catalogues of most fruit tree growers.

But—and this is a large “but,” for I can speak from intimate personal knowledge—one of the greatest of present day influences is the excellent instructions and practical illustrations of fruit tree management in all its stages, in every locality, and on the spot, to the people most interested, of the horticultural instructors of the various County Councils. Some people may—nay, some people do—scoff at this way of teaching; but when there are such men as instructors on the County Councils as Mr. Edward Luckhurst for Derbyshire, and Mr. A. H. Pearson and Mr. John Smith for Nottinghamshire, two counties of the Midlands of which I can speak, we may know that the very best of all instruction, both theoretical and practical, is given, and is, in its way, being acted upon all over the country.

What we have to do is to keep “pegging away” (that is really the reason of these notes) at the subject in season and out of season. We all know that to impress any lesson on the minds of children it is necessary to repeat it again and again until it is firmly fixed. All teachers act upon this principle, and all wise learners, too; for as we that are older are but children of larger growth, we find it necessary to have repeated over and over again any lesson which is of the first importance. Every student knows that in the getting up of any subject, if his reading is to be firmly impressed on his understanding, it is wise to write out what he has read, or is reading, and this amounts to a systematic and detailed repetition which has its results in fastening the subject unshakably in his mind. As G. H. Lewes once said, “The pen keeps the mind from staggering about.”

Take only two lessons (enough at one time), and let us try to drive them home. In many old orchards there are antiquated specimens of Apple trees with their tops in the sky and bare of branches below, practically barren and useless. Well, these, if headed down and grafted with well known varieties of strong constitution and good fruiters, can have their life renewed and be made exceedingly valuable in the future. No better instance of this act and its results could be given than that recorded by Mr. Wm. Bardney, in the *Journal of Horticulture* of December 8th, 1898, page 434, of the experiment in Ireland; and many similar beneficial results have been given by other fruit-growers, notably the practical instances, which anyone may see by a visit to Southwell, of the regrafting of old barren trees by Mr. Merryweather with Bramley's Seedling Apple.

The other lesson is the one of feeding. It was at one time, and is now in very remote places, the popular idea that all that is required to plant an orchard is to buy a few trees in the market, stick them in in any spare place, and then expect them to grow and fruit; and as to any old orchard trees requiring feeding with either liquid or solid manure, why that was the last thing thought of. These ideas are being slowly but surely driven out, and that largely by the influences I have given above. New life, then, by regrafting old trees, and better feeding of both young and old orchards by liquid or solid manure, are the two lessons we must all try to teach and to learn, again and yet again.—N. H. P.

SENECIO PETASITES.—This species makes a good companion for *S. grandifolius*, and is well worth growing, either as a pot plant, or planted in a border for the greenhouse during spring. It is a native of Mexico, and has large handsome foliage. The leaves are more or less reniform, with undulated margins and well-marked veins. They are often as much as 9 inches across, and make a striking feature among other plants. The heads of flowers are something similar to those of the common Groundsel, but larger, and are produced in large, loose, terminal panicles. It is of weaker growth than *S. grandifolius*, but the heads of flowers are quite as large. Like *S. grandifolius* it is of easy cultivation, little more attention being required when planted out than watering and cutting back annually. The height of the plant can be regulated by the pruning, plants 5 or 6 feet high being a useful size.—W.

TRICHOCESTRUM.

Though little grown by orchidists, this genus contains some very pretty species, and anyone who likes small yet showy blossoms may do worse than grow such as *T. albo-purpureum* or *T. tigrinum*, two of the best known and most useful in the genus. They thrive best in small pans or on blocks of Tree Fern stem, any great amount of compost about the roots being injurious, and the safest plan for them is a position not unduly shaded or far removed from the glass in the Cattleya house. They must never be really dried off, but during winter little moisture is needed, especially in dull weather.

EPIDENDRUM ENDRESI.

A native of Costa Rica, this is one of the loveliest little Orchids in cultivation; it is very rare. From the cylindrical stem the little erect racemes proceed, containing many flowers, these being pure white, with a few purple streaks about the lip. Whatever large plants of the species may do, it is certain that the small pieces in cultivation generally do not require large pots, nor can they stand much compost about the roots. Pans or pots nearly three parts filled with drainage, the rest made up with peat fibre and sphagnum moss, will suit it well. The growth will probably be most free in a shady and warm house, but from a proper cultural point of view a light not too sunny position in the Cattleya house will suit it best.

ODONTOGLOSSUM MINIATUM.

The peculiar habit of this Odontoglossot leads to its being ill cultivated in many places. The pseudo-bulbs are carried more distant from each other by the rhizome than is usual in the genus, and soon a plant potted in the ordinary way grows over the rim out of the reach of the compost. A flat-trellised raft would prevent this, and the young roots encouraged by the addition of new compost annually, just as they are being produced, the plant would gain strength and soon flower freely. In the one case it is starved for want of something to root into; in the other the warts of the roots are anticipated, as it were, by adding the compost just as they begin to push from the rhizome.

O. miniatum has a very remarkable appearance when in flower, the large, almost cylindrical, racemes of deep chestnut-brown blossoms being always attractive. Individually the latter are about 2½ inches across, the brown tint in the segment usually being relieved by a margin of bright yellow. The plant is a native of the New Grenadan locality, and likes a cool moist house, such as the majority of the genus thrive in. Plentiful supplies of water must be given to the roots all the year round, but especially during the summer months, when spraying or lightly syringing must also be practised. Peat and moss kept in a rough open state by the addition of pottery ballast and charcoal is the best compost.

ZYGOPETALUM PERRENOUDI.

In most of the hybrids in which any of the *Zygopetalums* of the Mackayi section have had a share of the parentage, the progeny has been of strong and vigorous growth. It is the case with the one above noted, which was raised on the Continent some years ago, and is occasionally seen in this country. For this reason I should have expected to see the hybrid shown at the Drill Hall some time since following the lead of others. *Z. Perrenoudi* is a pretty plant of free flowering habit, the spikes containing several flowers, the sepals and petals of which are olive green, the lip bright violet and purple. It was raised from *Z. intermedium* and *Z. Gaubieri*.

ODONTOGLOSSUM EDWARDI.

Very bright and pretty just now are the flowers of this Odontoglossot, though they are individually small. The colour is a bright rosy purple, quite unusual in this genus, and indeed not common in the Orchid family at all. Little difference will be found in the cultivation of this and the other members of the genus, but it likes larger pots than the crispum set for instance, and also a rougher compost, the roots being much larger individually, and very freely produced when the plants are healthy. *O. Edwardi* commemorates Mr. Edward Klabeck, an intrepid traveller, who sent home many beautiful Alpine Orchids.

CHARCOAL FOR ORCHIDS.

"J. T. B." has put his query in a different form to that answered in the editorial footnote on page 103. The question then was, "Is charcoal absolutely necessary?" and he proceeded to answer it by saying he had grown Orchids well without its aid. But his second query was answered in the footnote referred to before he put it. Does charcoal do any good? To quote from the footnote, "It takes up moisture easily, and gives it off again to the root spongioles, while the roots show their liking to it by clinging to it firmly." Very good; we must concede that charcoal of good quality is useful. Bad charcoal is like bad peat or moss or bad butter, or any other commodity. But we must not for this reason run down these materials as a whole.

Respecting "J. T. B.'s" argument as to decayed charcoal, he has not proved that this was the cause of the roots dying. The compost must be in a bad way when charcoal decays in it, and this would sufficiently account for the death of the roots. I am quite at one with "J. T. B." respecting the need of attention to small matters, and the habit of observation of these, which "J. T. B." has evidently practised to a large extent, is also to be commended. I hope that other Orchid growing readers will follow his lead, and let us hear of their treatment through these pages, and that "J. T. B." will take my short criticism in the spirit it is intended—*i.e.*, with a view to find out the real truth.—H. R. R.

ORCHIDS AT WOODHATCH, REIGATE.

When I saw very recently the most beautiful show of Orchids, but especially of *Dendrobiums*, Mr. T. B. Haywood has at his charming residence, I could but wish that Mr. Salter, the able grower, had permission to set the splendid collection of these up at the Drill Hall, where hundreds could see them, rather than only the very few privileged to visit them at Woodhatch. Not only is there a fine and varied collection, but the plants indicate culture and care, the highest order of excellence—indeed could not be excelled. What huge pieces of *D. nobile*, grand plants from 3 to 3½ feet through, literally masses of bloom; then what a show of the fine old *Wardianum* in variety, all so beautiful, so varied in markings, yet each one having the dominant characteristics of large flowers, tipped sepals, and intense orange coloured lips.

The Woodhatch form of *D. Ainsworthi* in numerous plants is a singularly attractive one, and the entire stock practically is here. Beautiful indeed are several plants of *D. splendidum grandiflorum*, and still richer in colour are *D. nobile nobiliss*, and the intensely hued *nobile Sanderianum*. Very rich-coloured also is *nobile roseum*. *D. Findlay-anum* is a lovely variety grown in baskets; and singularly pure, with markings of the clearest, is *D. nobile Amesiae*. But there are many others, and some good seedlings, with about 150 promising ones in various stages of growth yet to flower. *Phalenopsis grandiflora* is in grand form, so also is *Schilleriana*; and *Masdevallia tovarensis*, with small white spathes, is in great abundance. But the collection is a large one, and is well worthy of a special visit.—A. D.

DENDROBIUM NOBILE.

This old and useful plant will now, in many cases, be making a brave show, and where a fair number of plants is grown there is nothing that lends itself with better effect to any use it may be put to. The cultivation is of the simplest, and it is to be found growing in almost all kinds of positions and composts; but, like everything else, it amply repays any attention it may receive from the cultivator.

The cardinal points in the cultivation of *D. nobile* are abundance of heat and moisture when in active growth, and after they have finished a long rest in a dry house that does not go much below 50°. Care must be taken that the plant is not allowed to shrivel, neither must it be allowed to get soddened, or the roots will decay; keep everything scrupulously clean and the compost sweet, as no plant I know detests anything sour about their roots more than *Dendrobiums*. Those that require top-dressing, repotting, or rebasketing should have attention as soon as they pass out of flower. The compost used may consist of the best peat fibre, with all the small particles taken out, mixed with nearly as much live sphagnum moss, with the addition of some pieces of broken crock or bricks. Great care must be taken after a plant has been repotted not to give more water than is really necessary to prevent shrivelling, until the roots are seen to be running freely, and the young growths pushing strongly, or they are apt to turn black and decay.

There are many varieties, all of which are beautiful; but were I asked to name a few of the best, I should select amongst dark varieties *D. nobile nobiliss*, which is as yet without a rival; *D. n. Sanderianum*, *D. n. Harrisii*, *D. n. Cooksoni*, and the old *n. pendulum* and *Tollianum*; with such light varieties as *D. n. Amesiae*, *n. album*, *n. albiflorum*, *n. Ballianum*, and *n. Murrhinnianum*. There are many intermediate shades between the deep richness of *D. n. nobiliss* and the pearly whiteness of *D. n. Amesiae*.—J. BARKER, *Hessle*.

PRUNUS PERSICA VULGARIS ALBA FL.-PL.

THE value of the many forms of *Prunus* for the adornment of borders of some width, and of shrubberies, is becoming more and more apparent every year. During the early spring trees, young or old, make such a display as certainly cannot be excelled, if even it can be equalled. Then,

FIG. 53.—PRUNUS PERSICA VULGARIS ALBA FLORE-PLENO.

too, they are suitable alike for the small or the large garden—in fact, it is difficult to conceive where they would be really out of place. At the meeting of the Committees of the Royal Horticultural Society which was held on February 8th, Messrs. W. Paul & Son, Waltham Cross, received a first-class certificate for *Prunus persica vulgaris alba flore-pleno*, of which a spray is shown in the woodcut (fig. 53). It is one of the handsomest we have seen, and must, with its semi double pure white flowers, become an object of universal admiration. The widespread appreciation that is accorded to *P. Pissardi* on account of its chastely beautiful flowers and striking leafage is thoroughly deserved. This popularity is our reason for reproducing (fig. 54) a picture which, though it shows the profusion of flowers, fails to depict the beauty of the leaves.

PEAS.

IN the estimation of many people Peas are the daintiest of vegetables. There can be no question about their wholesomeness, and it is possible that a great percentage of persons, if asked which was their favourite vegetable, would answer, Green Peas. From scarcely any garden in the season are Peas absent, and I think gardeners often receive instructions to have as prolonged a supply as possible.

To obtain produce of the highest quality the best of cultivation must be given, or success cannot possibly be achieved. It is usual

to sow early varieties on a south border, and in this position, year after year, Peas will be grown with scarcely any change of crop for the soil. In a case of this description a dressing of lime has been found of great benefit, when the haulm has shown signs of becoming yellow unduly early, and when the crops have become lighter. This latter may possibly have been more the effect of continual manurial dressings causing the soil to become in a measure soured, rather than from a want of rotation in cropping. In any case, for all practical purposes, the desired result was brought about by the simple remedy of liming, and to practical men that is sufficient.

Good cultivators are agreed that a deep fertile soil rich in vegetable mould, and which has been manured rather heavily for a previous crop, is the ideal to be aimed at in growing Peas. I like to sow on ground which has previously grown a crop of Celery. In light soils it is often advised to sow midseason and late varieties in trenches. This is all very well if during a protracted drought water can be given copiously when needed, but if water is not plentiful, it is far better to sow in the ordinary way in drills, and afterwards to mulch the surface with any suitable materials which can be procured.

Sowing on a warm border in November is practised with success by some growers, though personally I have never been able to get these November sowings to produce Peas any earlier than those sown at the first favourable opportunity in the early part of the year, sometimes in January, more often in February. As soon as the first plants make an appearance above the ground another sowing of early varieties is made, and, with the exception that later varieties are used, this rule is carried out until about the second week of June. In July we usually sow some variety, such as William Hurst, to give a few dishes of late Peas.

For years the raisers of new varieties kept sending out early Peas which were ten days in advance of any other in cultivation, and according to calculations we ought to have been gathering green Peas out of doors at Christmas years ago. But "man walketh in a vain shadow," or the grower of early Peas does, if he makes no allowance for influence of climate and situation, and if he thinks that by variety alone comes salvation in the way of a heavy and precocious crop. In some establishments it is customary to begin the season with pot culture, and the many excellent dwarf sorts now in commerce should make this style of Pea culture more profitable than it was a few years ago.

The system of forwarding the first crops by means of turves, boxes, and such contrivances has been recently adverted to in the *Journal of Horticulture*. In numerous instances good results accrue, but care is required in the matter of giving slight shelter after planting out should the weather prove rough and cold. I still grow Ringleader for my early variety; some selections are much superior to others. With me William Hurst is far better than American Wonder, and the latter has been "scratched." Gradus comes next, and a really good Pea this is. Some may prefer Giant Marrowfat, but the former gives me the heavier crop, and must take precedence. Duke of Albany I cannot yet spare; while Dr. Maclean I always have, as it is one of the most prolific Peas, and is of fine quality. It has the fault, or some people would consider it such, of being pale coloured, but we can afford to overlook this on account of its obvious merits. Sensation has proved to be of exquisite flavour, but was not fruitful enough for our purposes, and so had to be discarded. G. F. Wilson still does good service with us, and another first-class variety is Autocrat.

What a number of really fine sorts of these 3-foot Peas there are. It is scarcely needful nowadays to grow any of the tall brigade, but I must confess to a liking for Ne Plus Ultra and Champion of England. For the last year or two I have had Conundrum as a late sort; it is too tall, but for an end of the season Pea is of very fair quality. Sutton's Latest of All has given me many late dishes. I have not mentioned Stratagem, Exonian, Oracle, and others, as it is difficult to particularise when there are so many that are excellent in every way.

Never have rows of Peas too near each other. It is far better to give more room and grow some other crop between the rows. Three foot varieties should have 4 or 5 feet, and the taller sorts space accordingly. We then can plant a row or rows of Potatoes, Cauliflowers, Spinach, and salads between. Staking is a matter of some moment, and must not be neglected. As soon as the young growths are 3 inches high it is wise to draw a little earth to them and stake at once; this gives protection, and the Peas take to the sticks better than if they are allowed to become a foot or so long ere anything is done. We make a practice of putting short boughs to the dwarf sorts, as this keeps them off the ground, and they crop much better for the little extra trouble, besides being so much easier to get at when gathering time arrives.

In some localities birds become a pest if preventive measures are not vigorously followed up. As soon as the plants push through the ground sparrows and chaffinches nip off the ends. Black thread strung along the rows we find a good safeguard. The worst comes to us, however, when the Peas are staked, as then the sparrow demolishes the leaves, and if it cannot be stopped the evil is most weakening.

Soot applied when the foliage is damp is one of the remedies, also a weak solution of petroleum sprayed over the rows with a syringe every other day for a time. When mice are troublesome trapping must be persevered in, or some other means should be taken to keep in check these pests, or great loss may result. The seeds can be slightly moistened and then shaken in some red lead before sowing. Paraffin sprayed over the surface of the ground where the Peas were sown has been the means of keeping them from their depredations.

Enough has now been said to show that to insure success with this greatly esteemed vegetable, much attention, perseverance, and watchfulness are necessary.—J. SHALFORD.

I FEAR, so numerous are Pea varieties now, so different do they grow on various soils, and so varied are they held in estimation by diverse growers, that it would be probably impossible for anyone to fix upon say a dozen of the best varieties. Moreover, persons who grow Peas know only those they grow out of the scores of varieties in commerce, hence their judgments in relation to the best varieties have to be tempered by restricted experience. I have been able to test several dozens during the past seven years, on various soils, and generally I have found those that are good in one soil have been good in another—and higher praise could hardly be given; but from out of so

FIG. 54.—PRUNUS PISSARDI.

many, as newer varieties come into commerce, there must of necessity be a gradual weeding, especially when, for various reasons, it is needful to compress the range of selection for trial.

My chief trial this year will be on the Surbiton group of allotments, where last year, in spite of the long drought, Peas did so well. As I grow varieties only that are suitable for the purposes of the allotment holders, who scrutinise the varieties very closely when at their best, none exceeds 3½ feet in height, and they are this season limited to fourteen only. These are Webbs' Senator, a grand second early; Sharpe's Triumph, Carter's Seedling, Sutton's Peerless, Webbs'

Wordsley Wonder, Dobbie's George Clelland, Sutton's Magnum Bonum, Johnson's Prolific Marrow and Magnificent, Sydenham's Majestic, Webbs' Astronomer, Sharpe's Queen, Dobbie's Gladstone, and Carter's Michaelmas. The sowing was made on the 8th, and thinly, a pint sufficing for a 90 feet row. Not only is thick sowing unfair treatment, but varieties cannot, when thick, display their true characteristics.—A. D.

FIRE BLIGHT ON APPLES.

I WAS naturally much interested in reading the account given by Prof. Wm. Smith (Leeds) at the R.H.S. meeting, of the diseased Apple shoots which I sent to Mr. Bunyard. I enclose separately an affected piece of the wood for your inspection, and send a few remarks. I dressed the affected parts with a mixture of sulphur and other matter, which causes the yellow appearance. I see there are numbers of blueish insects of considerable size. The tree was a large pyramid on Paradise, cut down close to the ground and grafted with Cox's Orange—graft two years old, growing strongly, but the leaves were not of a healthy colour in the summer, yet not "blackened," but grey and silvery. No sign of the bark being affected was visible till November, when cracks appeared and rapidly spread, the bark opening, rolling back, and disintegrating with remarkable rapidity.

Professor Smith says the disease is at rest in dry weather and winter, but we had no wet till November, which may account for it. The outward signs ceased after the sulphur application, but as I have no desire to spread an American disease among English Apple growers, this and the next tree which is also affected, will be grubbed up and burnt.—W. R. RAILLEM.

[The specimen is an object lesson, for which we are much obliged, and may at some future time illustrate and describe more fully. We found some bacteria belonging to the Micrococci, which is common on nearly all fungi in a state of decay and many other vegetable substances, and in mode of life wholly saprophytic. The whole and yet not sole cause of the graft dying is wet entering from the crown of the stock on both sides of the scion or graft between the bark and the wood, where the graft had never "knit" with the stock, but only at the base of the scion and lower part of the incision through the bark in the stock. The wet entering from the crown into the opening between the bark and wood of the stock on both sides of the large graft prevented the inner bark of the scion and stock "knitting," and the bark of both died back near the crown and from it downwards. That began the mischief, but the scion or graft would not have died unless something else had intervened—that was the spore of a fungus. We can clearly trace the beginning and end of the work, so far as the death of the graft is concerned, in the specimen. The fungus is still in the stock eating its life away between the bark and the wood—that is, living and growing on the cambial layer. The parasite devoured the cellular tissue at the base of the scion, cut off the descending assimilated matter, and the tree showed "fire blight" in the top. The fungus exists as a white felt-like growth between the bark and wood, and is the mycelial growth of *Polyporus vaporarius* or *Poria vaporaria*. About the dead scion is a quantity of dead matter and partly living on the size of the stock, and in this a number of eelworms, *Tylenchus obtusus*, commonly called root-stem eelworm, with the Micrococcus before mentioned. Between the dead bark and wood, where the fungus has done its work, are found a number of slate or lead coloured creatures, or, as you term them, "blueish insects." They are members of the Thysanura, family Poduridæ, by name *Achorutes purpurascens* (Lubbock), about one-twelfth of an inch in length, and perhaps the finest jumping animal in the world. It lives on dead or decaying matter. We found nothing more. Prof. Smith had of course only the leafy part to investigate, and gave opinion accordingly, it being very common to submit imperfect specimen for investigation, and thus place the investigator at a great disadvantage.]

PERENNIAL PHLOXES.

THE herbaceous Phlox is one of the noblest flowers in the hardy flower garden; no other plants give such a wealth of flowers for three months. To insure the best results, cuttings of sucker growths should be taken in April of each year, and inserted in cold frames in sandy soil, or if a frame is not available, the cuttings can be rooted under the shade of a north wall in a sandy bed. These cuttings, when well rooted, must be transplanted in June to a permanent bed, or other desired position. If the situation is not ready for their reception, they ought to be placed in a nursery bed for the summer.

Phloxes appreciate good treatment. A deeply dug, well manured soil, with heavy mulchings when the plants are in growth, and, if possible, liquid manure, go far to favour the production of large close spikes, with fine flowers of glorious colour. The stools ought not to remain more than three years. These may be divided in March and

transplanted, but such good results cannot be had as from the method previously advocated.

The varieties in the decussata section are innumerable, but I shall content myself with naming two dozen that I selected when in bloom last July, and all of which are superb, and these are: *Eclairer*, rosy lilac, centre salmon, a dwarf grower with a massive spike; bicolor, light salmon, dwarf; B. S. Williams, rosy crimson; *Comedie*, lilac, white edge; *Congress*, dark lilac, very distinct; *Defiance*, large pip, crimson; *delicata*, white, with a lilac eye; *Eugène Danzanvilliers*, delicate rosy lilac white; *Lucy Genin*, the best white; *L'Avenir*, deep salmon, dwarf bushy spike; *John Forbes*, pink, with crimson eye, very large; *Henry Bryson*, an improvement on coccinea; *Meteor*, purple lilac, distinct; *Major Houston*, intense purple crimson, fine spike; *Pantheon*, very fine; *Baccili*, rose, dwarf; *Aphrodite*, pure white; *amabilis*, good salmon; *Sir J. Douglas*, bright salmon scarlet; *Selection*, mauve; *Progress*, bright rose; *Mrs. A. Ritchie*, crimson; and *Sheriff Ivory*, light salmon, crimson eye.

When coming into bloom the spikes should be staked out, as light and air are essential to perfect development. The stems too are very brittle, and without support may be snapped by a gust of wind.—S. J.

SOUGHT AND FOUND.

(Continued from page 185.)

WE quickly found a great benefit through tapping that spring. The land would bear to fork out the beds of rushes preparatory to sowing a meadow mixture of grass seeds the following spring, and thus we reclaimed quite an acre of land as extra pasture. But to make more certain, I got Tillen to run two more short drains at right angles down the bank to the streamlet; and after that I put his draining capabilities to a severe test. I said, "You see how undulating the land lays in wrong directions. It seems to me to represent a tap for an immense extent of rising country above us. It will be impossible to drain it by an easy system, as there are substrata of gravelly loam or clay running parallel in wrong directions. It will be best first to lay a few deep drains longitudinally in the low inequalities of the land, and then feel our way as best we can by shallower ones to feed them from those beds of water weeds which you call 'smart grass' and 'cat tail.' That will keep you continually in work from December till the spring."

I will repeat the word "continually" (for you, Mr. Editor), feelingly, for the "Three Kings or Jack's Booth," and the "Dog and Partridge," not far off, had such attractions for "drainer John," who would much too frequently come to his work in a state quite unequal to the demand. "John Tillen"—very severely—"how often am I to tell you that I will not allow a man to come on my premises unless he is sober? Go home, I advise you, and come to your work when you are in a fit state." Further expostulations were useless to his stolen brain, so down he would throw his "graft," or other implement he might be holding at the time, and, in unparliamentary language I fear, tell me to do the draining myself for the future, and off he would go. But not often to act on my advice, "go home," for I often heard of his using the old cattle pound on Upton Green—in the next parish where he lived—as a half-way dormitory. "Tillen's bedroom" it is called by some, even to this day. It is sad to remember how this habit, in wet clothing often, shortened the life of a strong and most capable man. I missed him.

However, to cut a long story short, it took three years for us to complete so complicated a series of drains. I send you a peep at them by chart ("chaos!"). Please do not let your gasping basket get a glimpse of it, for, in that case, I shall be nonplussed, as by its means I can alight upon any one of the drains requiring rectification. They have behaved almost perfectly up to this day. The water-grasses have quite disappeared, and every inch of the land has become cultivatable. The dark lines on the map mark out the third series, the blue the second, and the red the first—the deep mains, which convey the under-plus water down to the river "ditch."

"Ditch! Edward Pearce, you insult it by calling a tributary of the Kennet a ditch!" "It is not a tributary!" quoth "Teddy," "it is the river 'Auburn,' from the Hampshire Hills, and comes past Darby Griffiths', Padworth House." "'Sweet Auburn!' river of the vale, and all the more reason why it should not be called a 'ditch.'" Good old "Teddy" Pearce, he was a deft hand at pruning and preparing a species of Willow largely planted and trained into tall stems hereabouts, on the margins of waterways, for the purpose of cricket-bats, erst for making Dunstable bonnets. "Teddy" gave me his pruning knife, a sort of two-edged blade, fixed at a right angle on the top of a long pole, two young Yew trees, and a Portugal laurel, as mementoes, not long before he died.—ROBT. FENN.

[We have returned the plan referred to, and are thankful we have not to undertake a similar task just at present. The system is admirable, and we fail to see how, after proper laying of the drains, it could possibly fail.]

RECENT WEATHER IN LONDON.—No one could have wished for pleasanter weather than that which prevailed in the metropolis on Saturday and Sunday. However, it was not to last, for on Monday and Tuesday we were wrapped in a dense fog, which reminded one forcibly of a November or a December day. Wednesday brought a change to more cheerful conditions.

— WEATHER IN THE NORTH.—The weather of the second week of March has been variable, rain and sunshine alternating daily with a generally high wind from the west. Sunday was the finest day of the season, with quite a spring-like sunny atmosphere. The forenoon of Monday was wet, the afternoon pleasant; in the evening the thermometer stood at 47°. The morning of Tuesday was dull and somewhat colder.—B. D., *S. Perthshire*.

— THE NATIONAL AURICULA AND PRIMULA SOCIETY.—The twenty-second annual report of the Southern Section of this Society reaches us from Mr. T. E. Henwood, Hamilton Road, Reading, the Hon. Secretary. The report is written in a congratulatory vein, but emphasises the desirability of enrolling fresh members. We observe that a packet of Alpine Auricula seed is given gratis to every member of the Society through the generosity of Mr. J. Douglas and Mr. C. Phillips. The annual show will be held at the Drill Hall, James Street, Westminster, on April 19th, 1899.

— THE MIDLAND CARNATION AND PICOTEE SOCIETY.—From the schedule of this Association, which has come to hand, we learn that the Exhibition will this year be held on August 2nd and 3rd. The prizes, cups, and medals offered for competition on this occasion reach a value approaching £200, and this sum ought to draw forth some superb collections of flowers. From the balance sheet and report embodied in the same book it is pleasing to see that the Society's affairs are in a satisfactory state. The Hon. Secretary is Mr. Henry Smith, Tenby Street, Birmingham.

— ACACIA LEPROSA.—This species can be grown and flowered well in pots; but to be seen at its best it should be planted against a pillar or other similar support, the main branches being tied close to the pillar and the side shoots allowed their freedom. In this way it grows freely, and quickly covers a large space. By cutting back the side shoots each spring after flowering much better results can be had, for long arching growths are made, 3 feet or more long, which are literally smothered with pretty golden heads of blossom for a month or more in February or March. In addition to its beauty whilst in flower the pretty, graceful growths hanging from a pillar are very attractive from July onwards until the pruning takes place.—D.

— PLANTING TOMATOES DEEPLY.—I have to thank "H. D.," who is a skilled cultivator, for publishing the results of his experience in reference to the effects of planting Tomatoes deeply or otherwise. He shows—and, as he states, from a far larger experiment than I had suggested—that burying stems deep is not productive of any better results than is shallow potting, no stem or adventitious roots being encouraged to form. This experience fully bears out what I have maintained—viz., that the roots which Nature furnishes to Tomato plants are, under ordinary culture, fully capable of sustaining the plants in carrying heavy crops, whilst burying naked stems to induce them to put forth new or adventitious roots is but utilising them at the expense of Nature's roots. "H. D." admits that even under his careful culture some seedling plants will have elongated stems; but even if so they will be found to have a plentiful supply of Nature's or basal roots all the same; and as he has shown conclusively, as the result of his published experience, that burying stems deeply does not increase crops, we are driven to the logical conclusion that elongated stems are buried to hide their nakedness rather than to help increase productiveness, although growers will fondly hug the illusion that in doing so such is their object. One would think that all plants were grown in pots to be afterwards moulded up the stems. Thousands of plants are put out from pots into the open ground, into soil beds, into boxes and troughs, the stems not being unduly buried, and these are never moulded up, yet they produce superb crops. Really where plants are raised by thin sowings stout and sturdy no one in planting thinks of burying the stems.—A. D.

— GARDENING APPOINTMENT.—Mr. Buckett, late of Norrystbury, Barnet, Herts, has been appointed gardener to H. Graystone, Esq., The Moor, Hay, Breconshire.
